DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J. LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

PUBLIC HEALTH REPORTS

VOL. 41 JULY 2, 1926 NO. 27

SIX ADDITIONAL CASES OF LABORATORY INFECTION OF TULARÆMIA IN MAN[1]

By R. R. PARKER, Special Expert, and R. R. SPENCER, Surgeon, United States Public Health Service

Six cases of tularæmia have occurred among the personnel of the Rocky Mountain Spotted Fever and Tularæmia Laboratory of the United States Public Health Service located at Hamilton, Mont. The first two became ill July 4, 1924, the third October 2, 1924, and the fourth, fifth, and sixth on May 18, 19, and 20, 1925, respectively.

Only two members of the laboratory personnel actually engaged in performing or assisting at necropsy of guinea pigs and rabbits infected with tularæmia or engaged in holding these animals or in handling ticks infected with tularæmia have escaped infection.

The 6 cases at Hamilton, Mont., increase to 17 the total number of cases of tularæmia in laboratory workers. Of the earlier cases 2 occurred in the plague laboratory of the United States Public Health Service in San Francisco,[2, 3] 6 in the Hygienic Laboratory of the United States Public Health Service in Washington, D. C.,[4] and 3 in the Lister Institute of Preventive Medicine, London, England.[5]

In all 17 cases the infection gained entrance to the body without leaving the slightest evidence of a local lesion or without causing glandular enlargement of any consequence. The clinical picture was more like that of typhoid fever than of any other infection, thus characterizing this uniform series of 17 cases of tularæmia as being of the typhoid type of disease, as defined by Francis.[3]

CASE I

R. R. S., male, age 36, physician in charge of the Rocky Mountain Spotted Fever and Tularæmia Laboratory, Hamilton, Mont.

Onset.—July 4, 1924, patient became ill with a feeling of general malaise, weakness, and indefinite pains in the abdomen. The next two days were marked by weakness and constipation, and a temper-

pation and increasing weakness characterized the febrile period, which continued for 34 days.

Skin eruption.—The period October 10 to 25 was also marked by a skin eruption which appeared first behind the ears and, spreading, took the form of a band about 3 inches wide across the back of the neck. The eruption gradually extended to the face, sides of neck and forehead, on October 18, it was noted on the elbows, and it finally appeared on the backs of the hands, on wrists, and fingers, and, to a slight degree, on the forearms and arms The eruption consisted of red, raised papules, mostly about one-fourth inch in diameter, a few were larger. The skin peeled on the areas of eruption and scaling reached its height about November 6.

Agglutination.—The agglutination titers of the blood serum for *Bacterium tularense* at various times following the onset of illness were: 6 days, 0; 14 days, 640, 21 days, 1,280, 7 months, 320; 9 months, 160; 15 months, 160. As in Case 1 a relapse (June 12 to 20, 1925) did not result in a rise of the agglutination titer, which on May 16 was 320 and on July 1 was 160.

Half time was spent at work November 22 to December 15; and after the latter date full-time work was done with difficulty owing to weakness and nervousness.

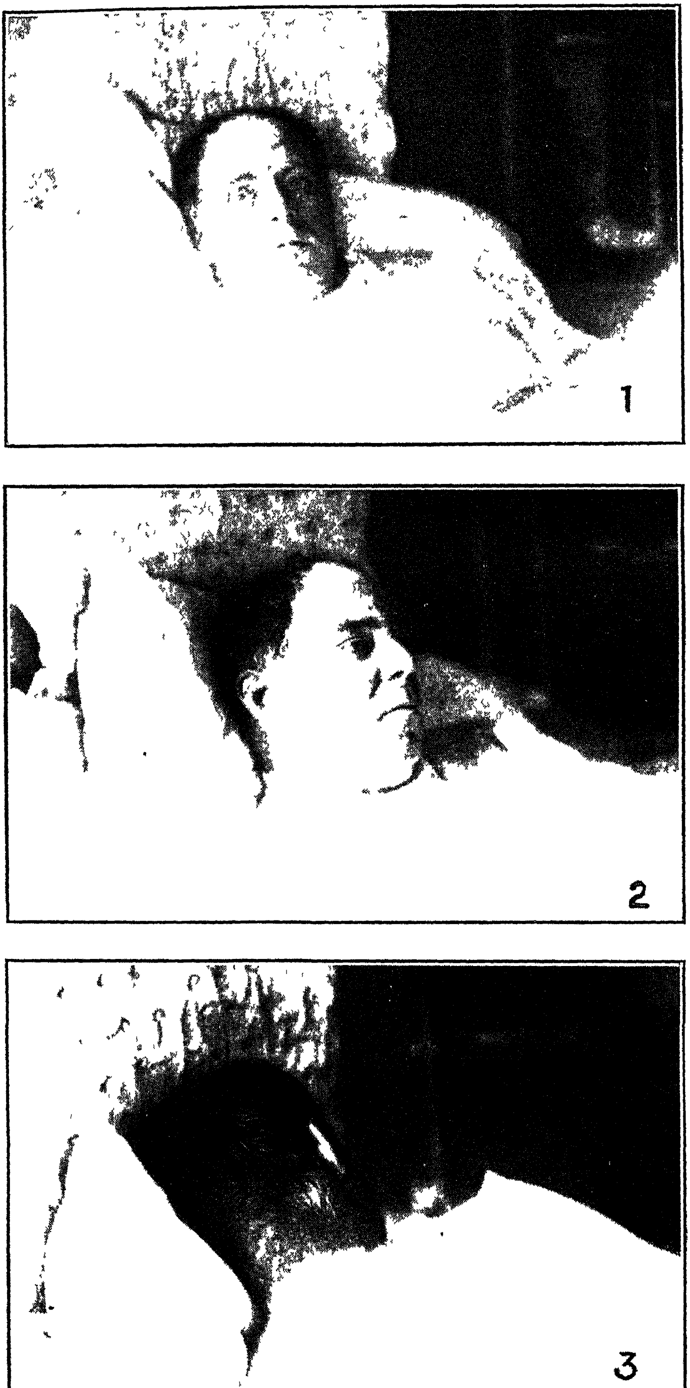
Relapse.—May 20 to 23, 1925, the patient experienced chilly sensations, general weakness, and slight headache, but no fever. Though there was increasing weakness he continued work until June 12, on which date (due probably to overexertion incident to a seven-day inspection and collecting trip in eastern Montana) a febrile attack began which lasted eight days and was accompanied by chilly sensations, headache, weakness, muscular pains, tenderness of the eyeballs, soreness of throat, and constipation; and for two days there was a scattered eruption of general distribution and exactly like that which accompanied the initial illness.

Temperature.—(See temperature chart.)

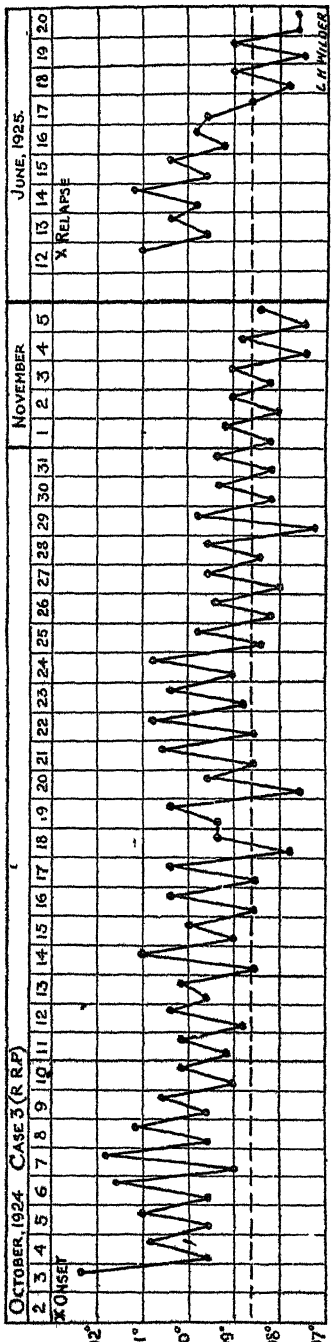
CASE 4.

E. W. M., male, age 33, laboratory assistant in the Rocky Mountain Spotted Fever and Tularæmia Laboratory at Hamilton, Mont.

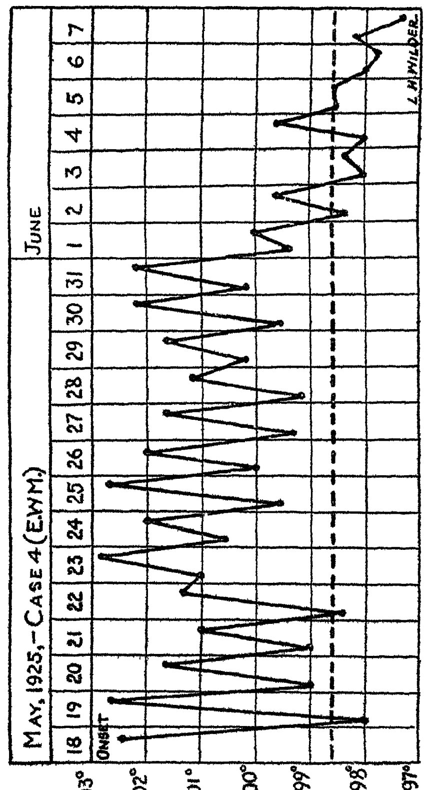
Onset.—May 18, 1925, at 9 a. m., became suddenly ill in the laboratory, with chill, headache, backache, and dizziness. Temperature was 100.4° F. at 11 a. m., when he was sent home. At 2 p. m. his condition was markedly aggravated He had fogged vision and deafness and did not respond when addressed unless roused by shaking. He was immediately taken to the local hospital and had to be assisted. In the right anterior cervical region there was much tenderness and slight swelling. There was a slight involvement of the



Skin eruption in tularaemia, Case 3 Photographs taken October 23, 1924



Temperature chart, Case 3



Temperature chart, Case 4

right tonsil. In the evening severe backache and shooting pains in the muscles of the legs made the patient very uncomfortable.

May 19, in the morning, owing to a return to normal temperature and an almost complete remission of symptoms, the patient left the hospital and returned home During the day there was headache, chilliness, cough, and sore throat, followed at night by a severe chill, fever, and sweating. Patient was up and about most of the day.

Owing to an almost normal temperature May 20 the patient was up and drove his car to the laboratory but did not perform any work. He complained of sore throat, coughed, and was chilly.

May 21: Throat very sore, had a chill; was up and about the house.

May 22: Throat and neck very sore, chilly; perspired freely at night.

From May 23 until temperature returned to normal the patient remained in bed.

Sore throat and soreness of the nasal passages were prominent symptoms throughout the illness. For several days the patient was unable to breathe through the nose; the passages were so tender that it could not be blown. The teeth were sore Constipation was marked during the entire illness. Nosebleed was noted five times. Deafness was noted while confined to bed Blurred vision was present from onset until several days after temperature became normal Abdominal pain was not marked and was confined to left side.

An eruption, like that of Case 3, appeared May 28 on the back of the neck and forehead and extended to the front of the neck, hands, and right knee. A few spots appeared on the arms and forearms. Small pustules appeared on the back and arms.

The patient returned to work July 5 and performed full-time duty, although with difficulty. Afternoon and evening rises in temperature occurred at intervals for several weeks. On June 30 a note was made that the spleen was palpable. Work has been continuous to the time of this report, but effects of the illness were still apparent in November, 1925.

Agglutination.—The agglutination titers of the blood serum for *Bacterium tularense* on various days following the onset of illness were as follows: 5 days, 0; 11 days, 160; 18 days, 320; 25 days, 1,280, 71 days, 320; 87 days, 320.

Temperature.—(See temperature chart.)

CASE 5

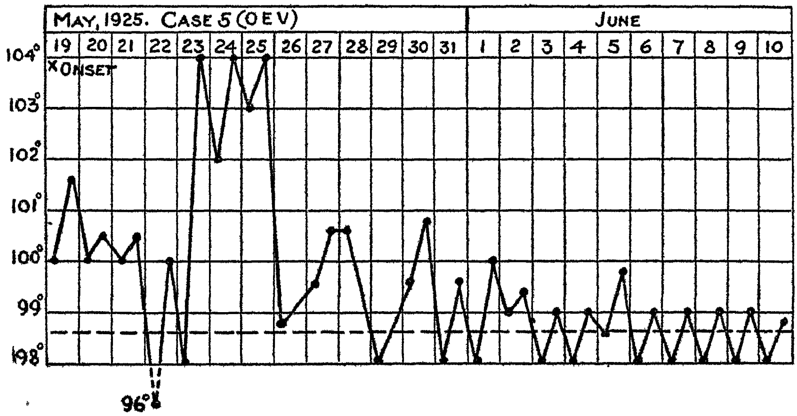
O. E. V., male, age 34, laboratory attendant in the Rocky Mountain Spotted Fever and Tularæmia Laboratory at Hamilton, Mont.

Onset.—May 19, 1925, the patient was feeling ill when he came to work and was noticeably sick at 11 a. m., but he continued to work until evening, when he took to bed. The onset was accompanied by

headache, pain in the eyes, pain in the back, abdominal pains, shifting pains in the muscles, chilly sensation, and fever. The patient remained in bed during his illness except that on the fourth day (May 22) there was an amelioration of symptoms and a remission of temperature to 96° in the morning, going to 100° in the afternoon, and the patient was up and about the house in the afternoon May 23 the temperature in the morning was 98° but reached 104° in the evening and reached 104° on the two following days.

The throat was sore during the first few days, but there was no cough. During the febrile period the chief complaint was of pain in the left side of the chest and back. At times it was painful to take a full breath. Sweating occurred during the night and after sleeping. Coldness of the feet was continual.

The patient did not return to work in the laboratory; he began work elsewhere on July 1, but it was not until September that he felt normal.



Temperature chart, Case 5

Agglutination.—The agglutination titers of the blood serum for *Bacterium tularense* on various days following the onset were: 4 days, 0, 10 days, 10; 22 days, 160; 31 days, 160; 63 days, 160.

Temperature.—(See temperature chart.)

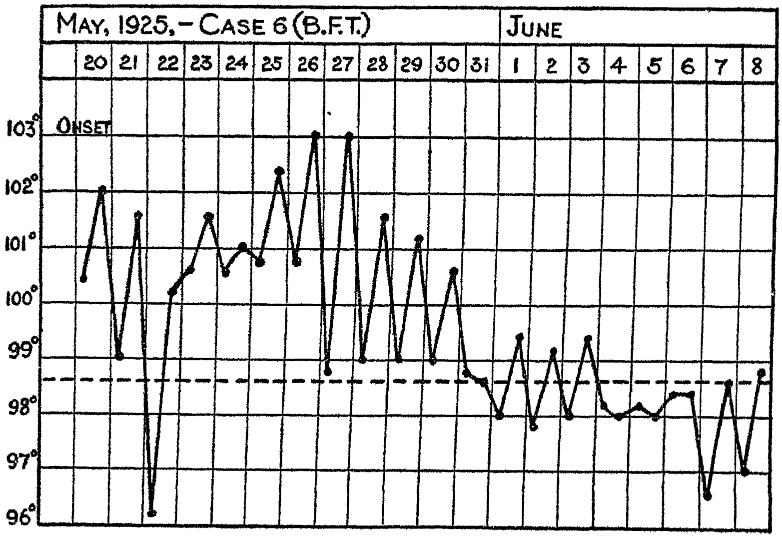
CASE 6

B F T., male, age 30, laboratory attendant in the Rocky Mountain Spotted Fever and Tularæmia Laboratory at Hamilton, Mont.

Onset.—May 20, 1925, although feeling weak and "stretchy," since the previous evening, went to work with a temperature of 100.4°, but went home at noon feeling very weak and complaining of stiff joints, sore muscles, stiff neck, and pain on taking a deep breath, had a chill, fever, and profuse sweating, his temperature reaching 102° in the evening.

His illness was marked by weakness, aching of the eyeballs, blurred vision, pains in the teeth, backache, soreness of the abdomen, "stretchy" feelings, chilliness, nosebleed twice on the sixth day, and coughing which began on the seventh day and continued throughout the eighth day There was no sore throat such as characterized the illness of E. W M.

The fall in temperature noted on the chart (May 22) was accompanied by a relaxation of symptoms to such an extent that the patient went to work on that date, sure that his illness was ended. He found, however, that work tired him so much that he returned home, went to bed, and remained until recovery He resumed full time work July 1, and by August 15 was feeling normal.



Temperature chart, Case 6

Agglutination.—The agglutination titers of the blood serum for *Bacterium tularense* on various days following the onset were: 3 days, 0, 9 days, 80; 16 days, 1,280. 23 days, 320; and 42 days, 320.

Temperature.—(See temperature chart.)

SUMMARY OF SYMPTOMS

(1) *Employment*—Our six cases comprised all but two of the total personnel of the laboratory actually engaged in performing or assisting at necropsies of guinea pigs and rabbits infected with tularæmia or engaged in holding infected animals or employed in handling ticks infected with tularæmia.

(2) *Onset.*—A sudden onset of rather high fever characterized the beginning of illness which, in most of the cases, occurred while the patients were at work.

(3) All six cases manifested the typhoid type of symptoms.

(4) *Remission of temperature.*—Cases 4, 5, and 6 illustrate the rule that, following the initial high temperature of one, two, or three days' duration there is a remission of temperature lasting for one, two, or three days, followed by a secondary rise to high temperature. This remission is accompanied by an amelioration of symptoms which reflects itself in the conduct of the patient and in the physician's opinion that the case is merely one of some ephemeral fever Of our patients, for example, Case 4 left the hospital and was up and about for several days; Case 5 was up and dressed; and Case 6 attempted to return to work

Cases 1 and 2 are without temperature records for the first few days, which probably finds its explanation in the same remittance of fever and temporary abeyance of symptoms. Case 3 showed a remission of temperature on the third day.

(5) *Absence of local lesions or glandular enlargement*—There was no local ulcer or sore or evidence of tick bite, nor was there evident enlargement of any lymph glands

(6) *Duration of fever.*—The febrile periods ended between the fourteenth and twenty-fourth days, except that in Case 3 it was 34 days.

(7) *Diagnosis*—Agglutination of *Bacterium tularense* by the patient's blood serum was negative in tests made during the first week as follows. On the third day in Case 6; on the fourth day in Case 5; on the fifth day in Case 4; and on the sixth day in Case 3. All cases gave positive agglutination in the second week and in all subsequent tests.

(8) *Eruption.*—Case 3 had a very definite skin eruption which appeared on the eighth day and continued until the twenty-third day. The eruption consisted of red, raised papules and was followed by peeling and scaling. A similar but less extensive eruption occurred in Case 4.

(9) *Tonsillitis.*—Case 2 was at first tentatively diagnosed as tonsillitis. Case 4 had a very sore throat throughout his illness, with slight involvement of the right tonsil, the nasal passages were also involved.

(10) *Convalescence.*—Convalescence was marked by weakness and a tendency to tire readily on exertion. Return to normal weight was slow.

(11) *Relapses.*—Cases 1 and 3, after 10 months and 8 months, respectively, had relapses of fever lasting six and eight days, respectively. These relapses in each instance followed unusual excessive exertion on the part of the patients while on trips away from home.

CONTACT OF OUR CASES WITH TULARÆMIA

Continuous experimental studies on tularæmia have been in progress at the Hamilton laboratory since the early spring of 1923, following the finding of natural infection in ticks.

Cases 1 and 3 were on the station staff at the inception of these studies; onset of tularæmia occurred, respectively, on July 4 and October 2 of the following year, 1924. Both performed numerous autopsies in the routine way on guinea pigs and rabbits dead of tularæmia and transferred the infection by inoculation or vaccination to healthy animals. In addition, Case 3 handled many infected ticks.

Case 2 was employed beginning February 27, 1924 The onset of his illness was July 4, 1924 He performed autopsies and assisted in the transfer of infection from infected to healthy animals

Case 4 was employed beginning May 24, 1924, onset of infection was May 18, 1925 He was continuously engaged in tick rearing operations and handled, during rearing, all ticks experimentally infected with tularæmia as well as the infected animals on which they fed. The use of rubber gloves for this work was impractical and contamination of the hands with animal urine and tick feces was unavoidable

Cases 5 and 6 began work, respectively, on April 20 and March 15, 1925, and the onset of their illness was, respectively, May 19 and May 20, 1925. Except that Case 6 occasionally held guinea pigs and rabbits for vaccination, these attendants were sedulously kept from contact with tularæmia work.

All cases were exposed at various times to such danger of infection as may have attended the handling of numerous wild ticks that were brought in or sent to the laboratory for various purposes. Tularæmia infection has frequently been found in such ticks.

POSSIBLE SOURCES OF INFECTION

The following possible means of laboratory infection were recognized and guarded against: (1) Contamination of the skin; (2) the getting of infectious material into the eyes; (3) contamination of the mouth or the ingestion of infected material; and (4) tick bite. Although not recognized as a definite source of danger, bites of infected animals were carefully avoided.

Materials known to be sources of contamination were: Tissues of infected animals; nasal secretions and urine of rabbits, tissue of infected ticks (especially the body fluid); tick excreta.

PRECAUTIONS TAKEN

Throughout the tularæmia work every possible precaution has been taken to guard against human infection.

For the most part, rubber gloves were worn when making autopsies or transfers of infection; their use by assistants was invariable. Assistants holding animals wore heavy rubber or leather gloves. During the infesting of rabbits and guinea pigs with ticks, and their

subsequent removal, the use of gloves by the person handling the ticks was not feasible This work was always performed by one of the writers when known infected ticks were used On all occasions when tularæmia-infected animal tissue or ticks were handled, thorough and immediate cleansing and disinfecting of the hands was rigidly insisted upon, whether or not gloves had been used. All abrasions were treated with iodine. All ticks, whether of known infected history or not, were handled solely with forceps Instruments were kept thoroughly disinfected and the boards used for autopsies were constantly kept in a barrel of cresol solution Tables used for autopsies and for the infesting of animals with ticks and for the removal of ticks were cleansed and washed with disinfectants immediately following use During the removal of ticks the table was frequently washed several times on account of the unavoidable scattering of tick excreta.

The writers were acutely conscious of the danger of infection and repeatedly impressed this danger on their assistants.

These laboratory infections, then, occurred in spite of unusual care and in face of the fact that each person was fully warned and acutely conscious of the risk.

Except Case 4, who reared ticks, assistants rarely performed any operation with tularæmia-infected animals or ticks except when assisting one of the writers.

MODE OF INFECTION

The portal of entry of *Bacterium tularense* in these cases is unknown, there being no evidence in any of them to indicate the primary seat of infection There was no local ulcer or sore, nor was there evident enlargement of the lymph glands.

Cases 1, 2, and 3 became ill while performing routine procedure—autopsies and transfers of infection from infected to healthy animals. Tick excreta and tick tissue can be excluded as causal factors in Cases 1, 2, and 3, since none of them had handled ticks for some time prior to the infection. Tick bites are also excluded. In all three the source of infectious material was undoubtedly an infected animal, but there is no evidence of the means by which infection was transferred, nor of the point of entry.

The circumstances which attended the infection of Cases 4, 5, and 6, however, were quite different from those of the 14 cases of laboratory infection which had preceded them None of them performed necropsy on infected animals As previously stated, Cases 5 and 6 had been carefully kept from any direct contact with tularæmia work except that Case 6 occasionally held animals while they were vaccinated. While the duties of Case 4 frequently necessitated the manipulation of known infected ticks (experimentally infected in the

laboratory), he had handled none later than the middle of March, two months previous to the date of infection

It is believed that the direct or indirect source of infection for Cases 4, 5, and 6 was a lot of several hundred ticks collected at our request from Owl Canyon, in the Bridger Mountains near Bozeman, Mont., by Prof. R A. Cooley These ticks, though subsequently found to be heavily infected with tularæmia, were supposed to be free from all infections, since no tick-borne disease had ever been reported within a radius of many miles of the point of collection. Supposed freedom from infection and a great abundance of ticks have made this canyon for many years a favorite place for the collecting of ticks for experimental purposes For the very reason that no infection was suspected, these ticks were turned over to the men concerned (Cases 4, 5, and 6) for customary procedure for the engorging of females This procedure is briefly described

1 *Infestation of hosts.*—The ticks were received in pill boxes, which were placed on an island in a pan of water and the ticks were transferred by forceps, without handling, to small stoppered vials From each vial they were transferred in a tangled mass to a shaved area on the belly of a guinea pig or rabbit and immediately covered by a brass gauze capsule which was secured to the animal by adhesive tape.

On May 5, one Belgian rabbit was infested, on May 6 two more were infested, and on May 8, seven guinea pigs. A total of 160 ticks were used, 12 to 23 being placed on an animal.

2. *Removal of ticks.*—The ticks were not removed until engorgement of the females was complete or unless a host animal died before this had been accomplished In the latter case the ticks were transferred to a new host. Ten days is the usual period required for full engorgement. The removal was performed, while sitting, by two persons working across a narrow table One held the animal on its back, grasping the front legs in one hand and the hind legs in the other, the animal being raised from and lowered to the table as necessary for the removal of the adhesive bindings. The second person first removed the tape and then carefully detached the ticks with forceps. The males were placed in a vial to be destroyed and the females in separate pill boxes for egg deposition. The ticks were not touched with the hands. The person holding the animal wore heavy rubber gloves. The person removing the bandages and ticks used the hands uncovered.

Partly fed ticks were transferred from dead guinea pigs to normal animals on May 10, 11, 13, 15, and 16. Engorged females were recovered from one Belgian rabbit on May 15 and another on May 16.

The original infestation of the host animals was performed by Cases 4 and 6 Following this and until May 16, all removals of ticks and transfers to new hosts were made by one of the writers, with the assistance of one of those two men. On May 16, however, the engorged females were removed from the second Belgian rabbit by Cases 4 and 5, the first and only time that Case 5 is known to

have come in contact with these ticks and animals, or with any source of infection The rabbit was held by Case 5 and the adhesive strappings and ticks were removed by Case 4. The entire procedure was performed under the observation of one of the writers.

During the removal of the tape the rabbit began a loud and prolonged squealing which continued until the removal was completed and lasted fully one minute Case 6, attracted by the squealing, came and leaned over the table and the rabbit to observe the cause of the disturbance. While squealing, the rabbit also passed urine, some of which was spattered on the face of Case 5, who was unable to release his hold of the rabbit His face, however, was immediately washed with cotton soaked in cresol solution and the urine was similarly removed from the table As soon as this rabbit could be released Case 5 thoroughly cleansed his face with soap and water.

During the period of the above-described operation, tularæmia infection in these ticks and animals was not suspected All seven guinea pigs infested on May 8 died between the 10th and 16th, and the ticks were transferred as indicated above. The lesions in the dead guinea pigs were not diagnostic, however, they were sufficiently unusual to justify transfers from three of them being made by spleen emulsion to normal animals. Of the latter, one died of typical tularæmia on May 18, and further transfers from the other two caused death typically on May 30. All three Belgian rabbits also died with typical lesions of spleen and liver and also complete involvement of the lungs. The lungs of one of the guinea pigs were also affected.

It is likely that the putting of these ticks on their hosts was an operation devoid of risk, because the ticks were hibernated, unfed adults (hibernated ticks do not pass excreta until fed), and the animals were normal. Obvious danger, however, attended the transfer of the partially fed ticks from the dead guinea pigs and the removal of the engorged females.

So far as is known this is a complete record of the contact of Cases 4, 5, and 6 with tularæmia-infected ticks and animals for a period of nearly two weeks preceding onset. These cases, therefore, appear to center around the procedure attending the feeding of the Bozeman ticks. Case 4 was most often exposed, and Case 5 on May 16 only. As previously stated, except when the ticks were first placed on their hosts and on May 16, when the females were removed from one of the Belgian rabbits, one of the writers performed the more dangerous procedure of transferring and removing the ticks, Case 4 or Case 6 holding the animals.

The obvious sources of danger were the nasal secretions and urine of rabbits, the excreta of the ticks, and the possibility of contamination with the body fluid of an injured tick. While admitting these

possibilities they do not seem adequate to explain these cases Case 5 was the only one to come in contact with rabbit urine Contamination with nasal secretions seems improbable, except perhaps as noted below

No tick is known to have been injured. Tick excreta was undoubtedly a highly potent source of danger, as this was present in abundance on each animal and always became more or less scattered when removing the tape and brass gauze capsule.

Another source of danger is to be mentioned in explanation of the possible method of infection in this special group of cases—i. e, inhalation or droplet infection This explanation assumes that these men inhaled the infection from the air around the Belgian rabbit from which the engorged females were removed on May 16, the air having become laden with infection expelled by this rabbit during prolonged squealing as noted above. In support of this view the following points are noted: (1) The fact that all three cases became ill within a 48-hour period, May 18 to 20, is suggestive of an unsuspected means of transfer of infection; for it scarcely seems probable that the routine safeguards against recognized dangers could have failed so utterly for three men on three different occasions within such a short space of time (2) Cases 4 and 5 were seated at a narrow table with the rabbit between them and were consequently in such close proximity to the rabbit that any danger of infection in the manner suggested was aggravated (3) Case 6, attracted by the unusually long and loud squealing came and leaned directly over the rabbit. (4) This is the only known instance in which these three cases were simultaneously exposed to the danger of infection, and their onsets were sufficiently close to admit the likelihood of a common source of infection and time of exposure. (5) The periods of incubation are not opposed to the occurrence of infection on May 16, the date the rabbit was handled. (6) Case 4, owing to his removing the adhesive strappings, was closest to the rabbit during the squealing; he was the first to become sick and was also the most ill. Case 6 was in less close proximity than either Case 4 or Case 5, and for a shorter time; he was the last to become sick and was also the least ill. (7) The rabbit died May 24, which was seven days following tick removal on May 16; necropsy revealed a general and marked involvement of the lungs. (8) During the prolonged and forceful squealing, infectious material from lungs or nose may have been expelled into the adjacent air.

The suggestion that Cases 4, 5, and 6 may have contracted tularæmia by inhalation necessarily assumes that a rabbit which had sufficient pulmonary involvement when handled May 16 to give off droplet infection would live until May 23.

Acknowledgment.—We are indebted to Drs H. D. Browning, Herbert Haywood, and G. A. Gordon of Hamilton, Mont., for clinical notes made while in attendance on these cases. The agglutination tests were made by Surg. Edward Francis at the Hygienic Laboratory, United States Public Health Service, Washington, D. C.

A CASE OF TULARÆMIA IN A LABORATORY WORKER

By Louis V. Dieter, Bacteriologist, United States Public Health Service

A case of tularæmia occurring in one of the personnel of the plague laboratory of the United States Public Health Service at Los Angeles, Calif., had its onset about January 4, 1926.

This is the eighteenth case reported of laboratory infection of tularaemia in man, the previous cases having been reported from laboratories located at San Francisco, Calif. (1) (2), Washington, D. C., (3) London, England, (4) and Hamilton, Mont. (5).

The patient had been working continuously since March 31, 1925, with strains of *Bacterium tularense* isolated by him from wild rats (6) received in the laboratory for routine examination for plague; he had performed numerous necropsies of rats and guinea pigs infected with these strains.

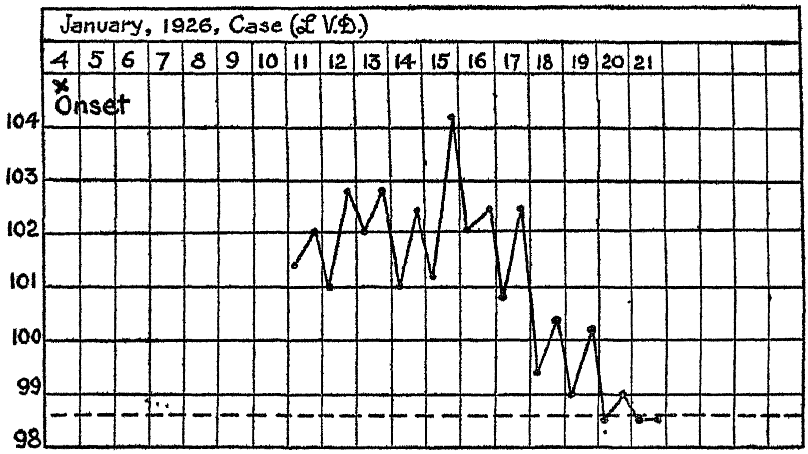
The patient (L. V. D.), male, age 40 years, bacteriologist in charge of the laboratory, became ill about January 4, 1926. Uncertainty exists as to the exact date of onset because the onset was not abrupt, but was manifested by a general feeling of malaise. About January 4 the patient first noticed a small papule on the back of the index finger of the left hand, near the middle of the proximal phalanx. This gradually enlarged during the next three or four days until it had the appearance of a small boil; when opened, pus escaped which showed the presence of *Staphylococcus aureus*. As tularæmia was not suspected, the pus was not injected into guinea pigs, so that it is uncertain whether or not the papule was the primary seat of the tularæmia infection.

The period January 4 to 9 was characterized by rise of temperature in the afternoons and evenings, chilly sensations, but no true chills, and a feeling of prostration and inability to obtain sufficient sleep. About January 9 the patient was forced to abandon work in the afternoons, and beginning January 12 he was forced to remain at home. From January 12 to 18 the symptoms suggested influenza and consisted of almost continuous headache, drowsiness, fever, chilliness during the day, extreme constipation throughout, and complete loss of appetite. There were occasional sharp pains in the right side of the chest and a continuous feeling of fullness and dull pain in the upper portion of the abdomen.

No glandular enlargements were noticeable at any time. Complete physical examination made by Surg H E Trimble, United States Public Health Service, failed to disclose glandular enlargements or other physical abnormalities.

The symptoms gradually subsided until, by May 1, 1926, no ill effects were noticeable except an occasional feeling of weakness lasting for a few days.

Agglutination —About 30 days after the onset, the patient tested his blood serum for agglutination of strains of *Bacterium tularense* which had been isolated from rats in his laboratory, agglutination occurred in dilution of 1·320, but not in higher dilution, and control serum reacted negatively About 50 days after onset he again tested his serum for agglutination of *Bacterium tularense* with the result that agglutination occurred in dilution of 1.1280, but not in higher



Temperature chart of case of tularæmia (L V. D) (laboratory infection)

dilution. The latter test was controlled by serums taken from two men belonging to the station personnel who were connected with outside work and who had recovered from attacks of influenza; their serums did not agglutinate in dilutions higher than 1:10

Five months after onset the patient's serum was tested at the Hygienic Laboratory, United States Public Health Service, Washington, D. C., and was found to agglutinate a strain of *Bacterium tularense* isolated from a rabbit obtained from the Washington, D. C., market, agglutination was prompt and complete in dilutions of 1:10, 20, 40, 80, 160, and 320, but not in higher dilutions.

BENZOL POISONING AS AN INDUSTRIAL HAZARD

Review of Studies Conducted in Cooperation with the Subcommittee on Benzol of the Committee on Industrial Poisoning of the National Safety Council [1]

By LEONARD GREENBURG, Associate Sanitary Engineer, Office of Industrial Hygiene and Sanitation, United States Public Health Service

I. THE CHEMISTRY AND INDUSTRIAL USES OF BENZOL

Benzene (C_6H_6) commercially called benzol, is a colorless, limpid, highly refractive liquid having a somewhat pleasing characteristic odor It boils at 80.2° C., yielding a very inflammable vapor, which on burning produces a smoky flame. Its specific gravity is 0 899 at 0° C. It is highly insoluble in water, more soluble in alcohol, and completely miscible with ether, acetic acid, and carbon disulphide. It is an excellent solvent for rubber, gums, fats, and resins of various kinds.

This interesting and highly important substance was discovered by Michael Faraday, in 1825, in the liquid produced by the compression of the illuminating gas obtained from the distillation of certain oils by the Portable Gas Co., of Paris, France Benzol was, however, probably known to Shellenz some 40 years earlier. In 1833 benzol was prepared by Mitscherlich by the destructive distillation of benzoic acid with lime. He determined its composition, measured its vapor pressure, and named the substance "benzin" or "benzine." [2] Leibig suggested the modification of this term to benzol to indicate its oily origin. Marignac recovered benzol in 1842 from the distillation of phthalic acid with lime, and Berthelot, in 1866, by heating acetylene.

---

[1] Since 1922 the Committee on Benzol (C.-E A Winslow, chairman, L Greenburg, vice chairman, W S Paine, secretary, H. Bradshaw, J. W S Brady, A C Fieldner, C. F Horan, L E. Weber, and J. M Weiss) has been conducting an extensive study of benzol poisoning as a hazard in American industry The results of the whole study will be published in a special bulletin for the National Safety Council by the National Bureau of Casualty and Surety Underwriters The review of the literature and the field studies were made by Dr J. W S Brady, Dr. J. J Batchelor, Mr J R Dexter, Dr J Newton Shirley, and the writer.

[2] The term "benzine," spelled with an "i," is now popularly applied to an entirely different substance (a mixture of C_6H_{14} and C_7H_{16}), a petroleum product

The presence of benzol in coal tar was first demonstrated by Leigh in 1842 and was confirmed by Hoffman in 1845. At that time Hoffman suggested the use of the name benzene for this substance.

In 1865 Kekulé announced the structural formula of benzene, and on this as a basis laid a foundation for the theories of aromatic compounds (1).

The earliest research on the commercial production of benzol from coal tar was that of Mansfield in 1849. In 1869 Caro Clemen and Engelhorn obtained patents on a process of recovering benzol from illuminating gas.

Illuminating gas, however, does not yield much benzol, without lowering its illuminating power, and it was only when similar processes were applied to coke-oven gas that substantial results were obtained.

In 1884 Carves obtained a patent on a process of removing benzol from coke-oven gas by a washing method The technical use of this method followed from the studies of von Hussener and later of Brunck, who set up the first plant in operation in Germany for the recovery of benzol in 1887.

Since that time the recovery of benzol from coking-plant gases has steadily extended, and now far exceeds recovery from city gas works.

The commercial uses of benzol rarely require that this substance be chemically pure. In practice, three types of benzol are used in industry, in addition to various other substances to which the name benzol is applied, although without justification from a chemical standpoint. The usual commercial products are the following:

Pure benzol—a clear colorless liquid of a charcteristic odor. B. P., 80.2° C.

Ninety per cent benzol.—So called because in the distillation of coal tar 90 per cent distills over at a temperature less than 100° C. It is composed of 80–85 per cent benzol, 13–15 per cent toluol, 2–3 per cent xylol, and sometimes contains as impurities traces of olefins, paraffins, sulphuretted hydrogen, and other substances

Fifty per cent benzol.—This substance contains 50 per cent of constituents which distill below 100° C. and 90 per cent of constituents which distill below 120° C. It is a highly mixed product, with only 40 to 50 per cent benzol, the remainder being higher homologues and impurities.

The other substances often called benzols are various toluols, xylols, and solvent naphthas.

Solvent naphtha.—This material is called solvent naphtha because it is used extensively (especially in England) for dissolving rubber. it is relatively free from benzol and consists largely of xylol, its homologues, and other unknown hydrocarbons (2).

In the production of benzol, the raw coal tar from the coke works is distilled in malleable iron distilling retorts using steam as the heating medium. Four fractions are usually recovered in this process Light oil, 1–3 per cent, medium oil, 9–13 per cent; heavy oil, 7–11 per cent; and anthracene oil, 12–18 per cent The remainder, comprising 52–60 per cent, is called retort pitch.

The light oil constitutes the basis for the manufacture of benzol. It is a liquid of sp. gr. 91–95; in color it is yellow to dark brown. Over 80 per cent of it consists of aromatic substance as follows Naphthalene, 16 per cent; benzol and its homologues, 74 per cent, phenol, 4–15 per cent; bases, 1–3 per cent; sulphur bearing substances, about 0.1 per cent; Nitrile, 0.2–0.3 per cent; acetone, cumene, indine, 1.0–1.5 per cent; Olefins, 3.5 per cent; Paraffins, 0.5–1 per cent; other unsaturated compounds, 1–1.5 per cent (3).

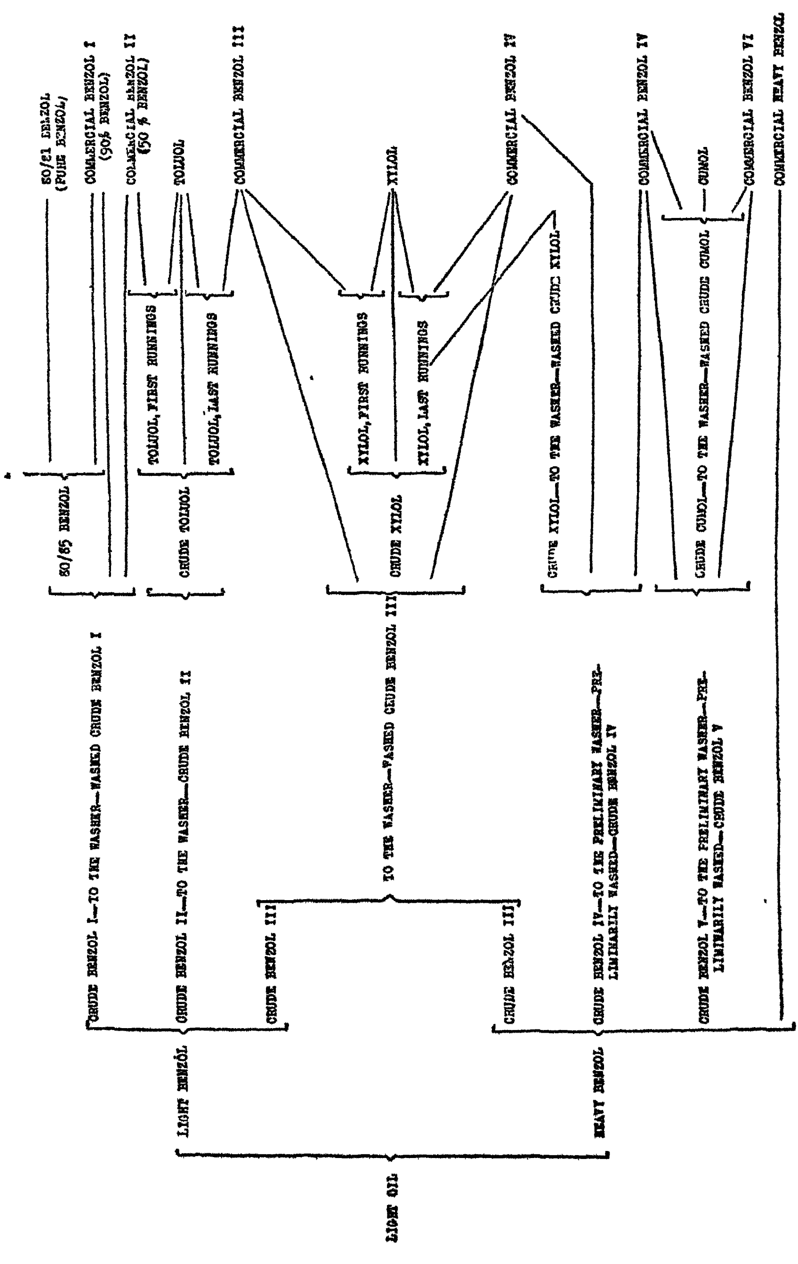
The method used for the recovery of benzol from coking-plant gases may be found in any complete handbook on industrial chemistry. The chapter by Dodge in Rogers' Industrial Chemistry has been freely drawn on in preparing the following brief summary

Essentially this process consists in removing the benzol from the coke-oven gas by taking it up in a wash oil and distilling the benzol from the wash oil by a continuous process.

The gas is cooled either by direct contact with water or in tubular coolers to about 70° F. It is then passed through a series of scrubbers (usually three). In these scrubbers, which are usually tall steel tanks or towers filled with wooden grids to present a large surface of contact, the wash oil takes up the benzol vapors After leaving the first gas scrubber the oil is passed through a heat exchanger, where it is heated by the vapors leaving the still to about 90° C., then through a second heat exchanger, where it is further heated by the debenzolized wash oil leaving the still to about 110° C.

It is then passed through the preheater and further heated by steam to 130° to 150° C. After this it passes to the still proper, which is of the continuous type, where the light oil is driven out by steam distillation, leaving the debenzolized oil, which leaves the base of the still, passes through the oil to oil-heat exchanger, the wash oil coolers, and is then ready to be pumped to the scrubbers for a second saturation with light oil from the gas

The light oil vapor mixed with steam after passing through the vapor to oil-heat exchanger is condensed and flows to the light oil tank after being separated from the condensed steam or water in the decanter. The yield of light oil from coke-oven gas is from 2¼ to 4 gallons per ton of dry coal carbonized, varying with the volatile content of the coal and much influenced by the type of oven and the heats employed. The relation of the amounts of benzol and toluol



—From K B Lehmann, Archiv f Hyg 75, 5.

produced are also influenced by the heats employed, low heats increasing the production of toluol and xylol.[3]

Prior to the World War the industrial uses of benzol grew steadily, but not sensationally. In Germany, according to Ullman (2), 100 kilograms of benzol cost 175–400 marks in 1882. By 1890 this price had been cut in half, and 4,000–5,000 tons a year were produced. By 1896 the price had dropped to 25–50 marks, and the production had risen to 7,000 tons. By 1901 the price was 20 marks and the production 28,000 tons, rising to 40,000 tons in 1904, and to 90,000 tons in 1908.

During the war the production of benzol was greatly stimulated by the demand for toluol along with which large quantities of benzol are commercially produced, a condition which has naturally led to the more widespread use of benzol as a starting point for the manufacture of various organic compounds, as, for example, in the anilin color industry and in the production of pharmaceuticals and chemicals for the photographic industries. In addition, benzol is used as a motor fuel by blending it with gasoline, and, above all, as an organic solvent in the rubber industry, in artificial leather manufacture and lacquer production, and in similar processes.

In considering the practical problem of the use of benzol in industry it is important to remember that two very distinct types of processes are involved. In such industries as (*a*) the distillation of coal and

---

[3] Following are the specifications for coke oven light distillates as prepared by the Barrett Co., one of the large producers of coal-tar distillates in the United States (4).

SPECIFICATIONS FOR COMMERCIALLY PURE BENZOL, NOT NECESSARILY NONCORROSIVE

(To be commonly known as "Commercially pure benzol")

Color.—The visible color shall be not darker than a solution of 0.0030 gm. of potassium bichromate in 1 liter of water. Comparison to be made in Nessler tubes, 50 c. c. size.

Distillation.—The product shall distill from start to dry within 2° C., within which degrees shall be included the true boiling point of pure benzol (80.2° C.).

The method of distillation shall be in accordance with method E-4, Jour. Ind. Eng. Chem. 10, 1008 (1918).

Acid wash.—The wash shall be not darker than No. 4 Barrett colorimetric scale. The test for wash shall be made in accordance with directions for test E-6, Jour. Ind. Eng. Chem. 10, 1008 (1918).

Acidity.—Finished product shall contain no "free" acid.

Specific gravity.—Specific gravity at 15.5° C. shall lie between 0.875 to 0.886. Specific gravity shall be determined by the use of Westphal balance.

SPECIFICATIONS FOR COMMERCIAL 90 PER CENT BENZOL

(To be commonly known as "Commercial 90 per cent benzol")

Color.—The visible color shall be not darker than a solution of 0.0030 gm. of potassium bichromate in 1 liter of water. Comparison to be made in Nessler tubes, 50 c. c. size.

Distillation.—The product shall start distillation (initial or first drop) at not below 76.2° C., 90 to 95 per cent shall distill at 100° C., all shall distill (end point) not above 120° C.

The method of distillation shall be in accordance with method E-4, Jour. Ind. Eng. Chem., 10, 1008 (1918).

Acid wash.—The wash shall be not darker than No. 6 Barrett colorimetric scale. The test for wash shall be made in accordance with directions for test E-6, Jour. Ind. Eng. Chem. 10, 1008 (1918).

Acidity.—Finished product shall contain no "free" acid.

Specific gravity.—Specific gravity at 15.5° C. shall lie between 0.875 and 0.887. Specific gravity shall be determined by the use of Westphal balance.

coal tar in the production of benzol, (*b*) the blending of motor fuels, and (*c*) the chemical industries, including oil extraction, dye and dye intermediates, manufacture of paints, varnishes, and stains, and of paints and varnish removers, benzol is used in large quantities; but the very nature of the industry demands that it be kept in a closed pipe-line system, any openings representing a loss of valuable vapors and making the system an inefficient one with a correspondingly large financial loss. In the class of plants mentioned, chronic benzol poisoning may be expected to play but a minor rôle, the hazard in acute cases being due to carelessness in the cleaning of tanks, breaks in the piping system, or similar accidents.

With regard to this first class of processes it seems certain that, with proper care in construction, maintenance, and operation, the use of benzol can be made sufficiently safe to warrant its employment. It

(Footnote 3 Continued)

SPECIFICATIONS FOR COMMERCIALLY PURE TOLUOL

(To be commonly known as "Commercially pure toluol")

Color.—The visible color shall be not darker than a solution of 0.0030 gm. of potassium bichromate in 1 liter of water. Comparison to be made in Nessler tubes, 50 c. c. size.

Distillation.—The product shall distill from start to dry within 2° C., which degrees shall include the true boiling point of toluol (110.4° C.).

The method of distillation shall be in accordance with method E–4, Jour. Ind. Eng. Chem., 10, 1006 (1918).

Acid wash.—The wash shall be not darker than No. 4 Barrett colorimetric scale. The test for wash shall be made in accordance with directions for test E–6, Jour. Ind. Eng. Chem., 10, 1008 (1918).

Acidity.—Finished product shall contain no "free" acid.

Specific gravity.—Specific gravity at 15.5° C. shall lie between 0.864 and 0.874. Specific gravity shall be determined by the use of Westphal balance.

SPECIFICATIONS FOR COMMERCIAL XYLOL

(To be commonly known as "Commercial xylol." Formerly known as noncorrosive solvent naphtha (benzol 160°).)

Color.—The visible color shall be not darker than a solution of 0.0030 gm. of potassium bichromate in 1 liter of water. Comparison to be made in Nessler tubes, 50 c. c. size.

Distillation.—The product shall distill not over 5 per cent by volume at 130° C., 90 to 95 per cent shall distill at 160° C., all shall distill (end point) at not above 180° C.

The method of distillation shall be in accordance with method E–4, Jour. Ind. Eng. Chem., 10, 1006 (1918).

Acid wash.—The wash shall be not darker than No. 12 Barrett colorimetric scale. The test for wash shall be made in accordance with directions for test E–6, Jour. Ind. Eng. Chem., 10, 1006 (1918).

Acidity.—Finished product shall contain no "free" acid.

Sulphur content.—The product shall be free from H_2S and SO_2 as qualitatively determined in test E–9, Jour. Ind. Eng. Chem., 10, 1010 (1918).

Copper corrosion.—Commercial xylol shall meet Standard Method Copper Corrosion test dated June 21, 1921.

SPECIFICATIONS FOR SOLVENT NAPHTHA (NOT NECESSARILY NONCORROSIVE)

(To be commonly known as "Solvent naphtha")

Color.—The visible color shall be not darker than a solution of 0.0030 gm. of potassium bichromate in 1 liter of water. Comparison to be made in Nessler tubes, 50 c. c. size.

Distillation.—The product shall distill not over 5 per cent by volume at 130° C., 90 to 95 per cent shall distill at 160° C., all shall distill (end point) at not above 180° C.

The method of distillation shall be in accordance with method E–4, Jour. Ind. Eng. Chem., 10, 1006 (1918).

Acid wash.—The wash shall be not darker than No. 12 Barrett colorimetric scale. The test for wash shall be made in accordance with directions for test E–6, Jour. Ind. Eng. Chem., 10, 1010 (1918).

Acidity.—Finished product shall contain no "free" acid.

is true that fatal accidents have occurred and will no doubt continue to occur in such processes, just as such accidents occur from the use of steam boilers The danger is, however, in both cases a controllable one, to be met by careful attention to safety provisions and not by the abandonment of the substance in question. To this phase of the subject we have therefore devoted but little special attention.

In a second group of processes represented by the use of benzol (*a*) in the rubber industry, (*b*) in artificial leather manufacture, (*c*) in sanitary can manufacture, (*d*) in dry cleaning, and (*e*) in connection with the handling of paints, varnishes, and stains, benzol is employed chiefly as a solvent or a vehicle, and as a part of the process it must be removed so as to leave the originally dissolved substances in place. The method of removal of the benzol is usually to permit it to evaporate. In most cases evaporation takes place while the compound is cold; in some, however, the compound may be warmed, a procedure which naturally removes the benzol with greater rapidity. The vapors arising when benzol is thus permitted to evaporate in the workroom atmosphere constitute the principal cause of chronic benzol poisoning. It is chiefly in plants of this type that we have carried on our studies

In the rubber industry benzol finds two exceedingly important uses In rubber tire building the metal core on which the tire is built is usually painted with rubber cement This cement is often made in considerable quantities, for, during the course of the workday, large amounts of this substance are used. The rubber, after being compounded in the general compound room, is brought to the cement house, where it is cut into small pieces (about 4 pounds) and broken down in a pair of heated "break-down" rollers. It emerges in a rather porous condition and warm. It is then placed in a vertical tank containing benzol and provided with agitators and is stirred continuously until it is in solution. It would appear that this process might easily be conducted without hazard, but in making our studies we found one plant in which this was far from being the case.

In the further steps of tire building benzol is used in many plants. The layers of rubberized cord or cloth are carefully placed on the metal tire-building core, each layer being moistened with benzol prior to the application of the next layer of fabric. In addition to these two uses of benzol in the rubber industry there are, of course, many others. In fact, this substance has found very wide use due to its excellent solvent properties for rubber.

In the manufacture of so-called sanitary tin cans solder is not used to fix the top and bottom of the can to the cylindrical body portion, but these are crimped together instead, and it is necessary to provide some means of rendering the can absolutely air-tight. This is most

successfully accomplished by means of a rubber cement. The can ends are punched from sheet metal by means of an automatic punch press and then raised to the feeding end of a coating machine. In this machine the can end is held on a revolving vertical spindle, and as it revolves a very fine stream of benzol rubber cement is forced under air pressure on the can end. After the disk has made one complete revolution and a thin band of the cement is in place, the disk is automatically ejected and slides down a small incline to an oven, in which the benzol is largely but by no means completely evaporated. The can ends emerge from this oven in a warm condition and with benzol evaporating from the ring of cement about the periphery It is at this point that the inspectors, usually young women, are exposed to the benzol fumes while inspecting, cleaning, and packing the can ends

In the artificial leather industry, benzol is used in immense quantities. In producing artificial leather, cloth is fed through a machine at one point of which is a knife blade stretching across the full width of the cloth. Here the compound with which the cloth is to be coated is applied. This compound is a viscous liquid consisting of nitrocellulose and castor oil which is dissolved in ethylacetate or other suitable solvent. Benzol, in proportion of approximately 60 per cent, may be added as a diluent and derives much of its value from the fact that it is miscible with the other solvents and also with the nitrocellulose. The required color is given to the compound by the addition of suitable pigments, and the whole batch is thoroughly mixed until a homogeneous fluid results. This batch, when ready for delivery to the coating machine, is evenly spread over the cloth as it passes under the knife edge. The cloth next passes to an inclosed heated chamber in which the volatile substances are driven off, the colored nitrocellulose remaining behind on the cloth. The cloth emerges from the chamber in a warm condition and, although rather dry, still has a certain amount of solvent evaporating from its surface. It is this solvent which is still evaporating from the surface of the cloth and the solvent vapor escaping from the hot chamber which create a poison hazard. There is also a certain amount of evaporation which takes place from the surface of the pool of compound directly at the knife edge where it is being applied to the cloth, and this further increases the benzol content of the workroom air.

In the process of dry cleaning, the clothing and other articles to be cleaned are placed in horizontal tanks containing benzol, in which, by the continuous agitation of the tank, the grime and grease are dissolved. After this treatment the clothing is placed in centrifugal extractors by means of which the excess of benzol is removed. The articles are then taken from the extractor and, as a rule, are placed

in a warm-air cabinet in which the last traces of the benzol are volatilized. During this complete procedure from the time the washing tank is opened in order to permit of the addition of the articles to be cleaned to the time when the clothes are benzol free there exists much opportunity for the dissemination of benzol fumes in the workroom air, with the attendant dangers associated with these vapors.

Lastly, in the use of paints and penetrating stains, wood dyes, benzol finds very widespread use. This substance has deep penetrating power and for this reason is of great value for such purposes. When the paints are spread on the surface to be coated or treated, the vehicle evaporates, leaving the pigments behind In the case of paint and varnish removers, the compound is permitted to remain on the surface to be cleaned for some time preparatory to the process of scraping the surface. The hazard involved in this procedure must be small as compared with that in the use of benzol containing paints. It has been shown that the volatility of benzol is markedly affected by the other substances present in paint removers. Of 8.7 grams of benzol exposed in an open Petri dish, 98 per cent was evaporated in 100 minutes, whereas of 8 9 grams of a mixture composed of 55 per cent benzol, 45 per cent acetone, and 3 per cent paraffin only 0.4 per cent was evaporated in 300 minutes at the same temperature.[4]

II. ACUTE BENZOL POISONING

As in the case of so many toxic substances used in industry, instances of benzol poisoning fall into two rather distinct groups—acute and chronic poisoning, respectively. As a rule the cases of acute poisoning are obvious and readily diagnosed from a consideration of the history, symptoms, and circumstances surrounding the individual case. Some cases of acute benzol poisoning are due to the specific toxic effects of benzol, while others are undoubtedly due to benzol asphyxiation caused by the greater density of benzol vapor as compared with air, with the consequent exclusion of the air. Cases of asphyxiation are most likely to occur when a worker enters an inclosed space such as a tank which formerly contained benzol. Cases of chronic poisoning, however, are generally more obscure, the history of exposure is not so definite, and the symptom-complex and signs of poisoning as a rule are not so evident.

Acute benzol poisoning has been generally encountered in industrial practice, although case reports of benzol taken with suicidal intent or poisoning occurring in its nonindustrial application are also relatively frequent The early literature with reference to benzol as an industrial hazard is not unnaturally based on continental experience and later to a lesser extent on that obtained in England.

[4] Personal communication from Weiss and Downs.

It was not until the outbreak of the World War that benzol poisoning to an alarming extent manifested itself in the United States as a result of the wholesale production of benzene and its derivatives as by-products of the benzol manufactured for war purposes. Attention was first drawn to this problem in America by Alice Hamilton in her reports on industrial poisons encountered in the manufacture of explosives in this country (5) Prior to the war, however, Selling and others had reported on the toxic effects of benzol manifested in workers engaged in certain industries.

In 1862 there appeared in the Lancet (6) under the title of "A new industrial poison" a case report of a death due to the inhalation of vapor and the ingestion of a fluid containing "benzole." The patient became sick and drowsy, somewhat cyanotic, and developed a feeble pulse, the symptoms being those of gastro-intestinal irritation. On autospy no trace of the toxic substance was found in the stomach Congestion of the brain, lungs, and liver was present, and congestive patches were present in the gastric mucosa. The coroner decided that death was due to prussic acid, inasmuch as the "benzole" was found to contain some of this substance Benzol as such, however, appears to have played a part in this fatality.

Two very early cases of benzol poisoning are recorded in St. George's Hospital Reports for 1877–78 (7). In each of these instances a small amount of benzoline (benzol) was swallowed by mistake. Emetics were used apparently with success, although no mention is made of the outcome. In 1889 Averill (8) reported a case in which 3 to 4 drams of benzol in castor oil was taken by mistake with toxic effects. The patient recovered after receiving medical attention.

In 1910, at the International Congress of Industrial Hygiene, Rambousek (9) presented a report of 22 cases of acute benzol poisoning, 18 of which proved fatal. Most of the acute cases appear to have occurred in or around coal-tar stills and benzol tanks. He cites a case taken from the Factory Inspector's Report of Germany, for the year 1902 (10), of a worker who was overcome while painting the interior of an iron reservoir with a benzol-asphalt paint. In 1903 several other acute cases were recorded. While cleaning an extracting apparatus, a workman was fatally overcome by benzol fumes (11). Another worker who forgot to open the cold-water valve of a condenser was overcome, with fatal results, by the uncondensed vapors which were dispersed in the general room atmosphere (12). Another interesting case is recorded in the German Factory Reports (11) in which a worker engaged in the manufacture of antipyrene inhaled the concentrated benzol vapor with fatal results

Several cases of poisoning by swallowing benzene have been recorded Simonin (13) reports such a case of accidental poisoning in which the patient survived, but developed an odd type of skin

condition consisting of swelling and edema. Schmitz (14) records a fatal case of poisoning by injestion, the autopsy findings of which will be discussed later in this report Hetzer (15) reports an unusual case in which a man who had swallowed benzene was given prompt medical treatment and survived, but developed an intense toxic gastritis and later pyloric stenosis. Nick (16) cites the case of a workman who swallowed 80 grams of commercial benzene and developed the usual acute symptoms. Five cubic centimeters of a 10 per cent lecithin emulsion (Merck) was given by intravenous injection, about two hours after poisoning resulted, and definite improvement was noted within an hour. Thirty-six hours later all outward signs of poisoning had disappeared.

In the Prussian Factory Inspector's Report for the year 1904 (1) two fatal cases are described in workmen engaged in cleaning out a tar still. Death was due to fumes presumably of benzol, although this was not definitely established. In 1905 (17) three cases of poisoning, one of them fatal, occurred in a rubber factory where a benzol rubber composition was being mechanically spread on fabric The fabric, after being coated, passed over a long heated plate to facilitate drying, a procedure which gave rise to the production of large quantities of benzol vapor in the room air. The same year, 1905 (18), a worker was overcome by benzol fumes while cleaning out an empty tank which had contained crude benzol. A short while previously another similar case had occurred in the same factory. In another plant (19) two other cases of unconsciousness occurred, the workmen being overcome on entering a tank containing heavy oil used for cleaning purposes. In the Report of the Union of Chemical Industry for the year 1905 (20) a case is cited in which a night workman neglected to open a valve which allowed benzol distillate to flow into a collecting tank, and 8,000 liters of benzol overflowed. The workman was found dead in front of the building. Lewin (21) reports an interesting case in which an extracting vessel was being cleaned. The vessel had contained naphthaline and benzine, but had been empty for 22 hours. Furthermore, it had been washed out three times with cold water and twice with steam, then again allowed to stand all night filled with cold water. The workman who entered the tank was equipped with a pipe supplying compressed air. Despite these precautions he was overcome by the fumes of benzol which had dropped into the tank from a leaking overhead pipe. Several men who attempted to effect a rescue were overcome and one of the rescuers died within ten minutes after exposure. The original workman was finally saved by an engineer equipped with a breathing helmet. Dr. Alice Hamilton (22) reports a similar case which occurred in England. A benzene tank car had been emptied, washed with water, steamed, filled with water for 20 hours, then

washed out twice again boiled for 12 hours, and finally left for 10 days with the manhole open Despite these precautions the workman who entered the tank collapsed, and although he was removed in time, one of his rescuers succumbed These cases have led to the belief that muscular exertion tends to increase the susceptibility to poisoning and to decrease correspondingly the prospects for recovery in acute cases. That such a belief is tenable is illustrated by the many cases in which a passive victim who has been rendered unconscious by the benzol vapor recovers despite his relatively prolonged exposure, while an active rescuer succumbs with a fatal termination despite his relatively brief exposure to the same concentration of vapor. Lehmann stresses individual susceptibility as the important factor in such cases That marked variation in individual susceptibility does exist is amply demonstrated by clinical and experimental observation, findings with which we are in accord. It is possible and perhaps even likely, however, that in some cases the degree of activity of the subject plays a part in determining the outcome of any particular exposure.

Yet another case may be cited of a worker who was rendered unconscious while inspecting a benzene still. Two fellow workmen who attempted to rescue him were also overcome, one of them dying. All three had been negligent in failing to observe the rules requiring that the still be blown out with steam and that a watch mate be on guard outside for any emergency (23).

Two fatal cases are reported (24) from a factory where thick tar was being distilled under pressure and where the air pumps got out of order. The steam and the tar constituents were cooled and led into a drain. Near this drain was a ventilating shaft, and the two workmen were killed by the vapors rising through this vent duct. In 1908 two other fatal cases (25) occurred in the cleaning of a railway tank car The tank had been washed, but the workman, who entered with the approval of the foreman, succumbed and his mate on guard at the manhole had apparently gone in to his assistance as he also was found within the tank.

In 1909 (26) a very interesting case of benzol asphyxiation occurred in a coke-oven plant. Benzol was being collected in two large iron receivers. In order to control the valves it was necessary for the worker to enter a roofed-over pit in which the valves were located. During the filling period, the tank manholes were kept open. The only ventilation was that provided by two shafts which also served as entrances to the pit. A worker entered the pit to manipulate the valves and some time later he was found huddled up on the top of the receiver holding the valve by one hand. Later he fell to the bottom of the pit Three fellow workmen who went to his rescue

were affected by the fumes and were forced to retire. A fourth worker was lowered with a rope, but with immediately fatal results. Finally, with the aid of a smoke helmet, a rescuer brought up the corpse of the first victim. Rambousek (9) suggests that possibly other volatile substances contributed to the poisoning in this case. In his summary he also describes the similar case of a foreman who failed to regulate a condensation system so that benzol fumes were permitted to escape, to which he succumbed as did also a rescuer, the foreman's case terminating fatally. Yet another such case is given in the Annual Report of the British Chief Inspector of Factories (27) in which a sudden change in pressure caused a more rapid distillation of benzol vapor than the condenser could deal with, so that the workman was overcome by the excess uncondensed fumes Although he was resuscitated, he again succumbed when he returned to his work two nights later, the incident proving fatal

Rambousek cites another fatal poisoning which occurred when a worker in an anilin factory inhaled the vapor from benzol which escaped from leaky valves. Beisele (28) records the case of a man who died while painting the inside of a tank with tar dissolved in benzol, the usual acute symptoms being followed by death within five minutes of exposure. Buchmann, in 1911 (29), reported an acute case of poisoning produced by benzol escaping from a piece of defective chemical apparatus. In the German Factory Inspector's Reports (30) for the year 1912, three cases of poisoning are described, two of these terminating fatally. One case was that of a workman painting the interior of a barrel with benzene containing paint; another that of a workman in a cleaning establishment who entered the washing machine in which there still remained a small quantity of benzol; and one in which the cold water had not been turned on for the condensation of benzol vapor, with the resultant escape of benzol fumes and the death of the workman. Heffter (31) reports a case of an assistant manager who, while opening a stopped pipe, succeeded in starting the benzene flow but was unable to stop it. Benzene splashed over his clothes, but he nevertheless continued working while two helpers who were with him felt sick and were obliged to leave. The foreman finally fainted and died, although he received three hours' treatment with oxygen. Albaugh (32) cites a possible case of fatal poisoning in a young man employed as a spray painter in a varnishing department. Robinson (33) cites three cases of death from benzol fumes where employees persistently entered tanks regardless of rules requiring the removal of fumes and without protecting themselves with life lines and other protective devices provided by the employers He reports one of the cases in detail. A workman entered a tank which had but a slight odor of benzol, grew dizzy, crawled out and sat down on the ground

outside In a few moments, however, he became unconscious and never recovered

The demand for toluene for the manufacture of explosives during the World War led to the establishment of many plants for its production. Along with this enormous production of toluol, benzol was produced in very large quantities, and because of this wholesale increase in the handling of benzol, cases of acute poisoning suddenly increased By 1916 Alice Hamilton (5) had already collected and reported 14 acute cases, with seven fatalities, in this country. At that time she placed benzene poisoning third on the list of industrial poisons Of the 7 fatalities, 5 occurred among workmen in or around stills, the other 2 deaths occurring in the sulphonation of benzene during the synthetic production of phenol. Doctor Hamilton's first two cases were of steam fitters who were repairing pipes inside a benzene still. The still, before the repairs were begun, had been emptied and washed and was believed to be free from any dangerous concentration of benzol vapor Shortly after entering the still, one of the men became unduly hilarious and excited, singing and shouting. Attempts were made to get him out through the narrow manhole, but he was so irrational that it took 10 minutes to rescue him. At first his fellow workman within the tank helped in the rescue, but later he also succumbed to the fumes and was rendered unconscious. It took about 20 minutes to get this second workman out of the still, at the end of which time he was dead. In another establishment two workmen entered a still which was supposed to be free from benzol but apparently was not, as they soon succumbed and lapsed into coma. Vigorous treatment was administered, but the one who had been in the still for the shorter period did not survive. Yet another case was that of a workman who attempted to stop a leak in a still but was overcome by benzol fumes, with fatal results. Two fellow workers who went to his aid were also overcome, but survived. In the sulphonating room of a factory the sulphonated benzene flowed into a "liming vat" and apparently had carried some benzene over with it which volatilized because of the heat. A workman was found dead beside the liming vat, and benzol fumes were shown to be escaping from the liming vat, the sulphonating kettle, and the supply pump in the same room.

Harrington (34) reported the cases of two steamfitters, repairing pipes in a benzene still which was provided with a small manhole No mention is made of the preliminary cleansing of the still, but a fresh air supply was introduced through a 2-inch pipe under 60 pounds pressure. Within 45 minutes the older workman, aged 35, "acted crazy," becoming wildly excited and later unconscious In the attempt to get him out through the manhole, which took 20 minutes, the younger man succumbed and was found dead.

Dworetzky (35) described the interesting history of a peculiar epidemic in a large Russian rubber factory On March 25, 1914, many workers came down with headache and dizziness, nausea and vomiting, some falling to the floor unconscious. Several of them had to be sent home or to the hospital Next day the workers who had returned were put to work in another room where nothing had occurred the previous day. Strange to relate the same group of symptoms again appeared, with a total of 102 persons affected. By the fourth day over 230 persons were involved; and after nine days of trial, the factory (employing 17,000 persons) was forced to close. The workers ascribed the symptoms to the use of a new rubber solvent. At first they said a colored odoriferous solvent was used which caused no trouble. When the solvent was changed, however, to a clear and less odorous one, the outbreak was precipitated. The management pointed out that this was unlikely, for they substituted only the very highest grade of Baku naptha products The medical authorities (Bechterew) decided that the outbreak was one of hysteria or of benzene or benzol poisoning, together with hysteria. At the same time, in the tobacco factory of "Bogdanow" 18 workers (16 females and 2 males) came down with very similar symptoms, and in the tobacco firm of "Schaposchinkow" 20 workers fell unconscious to the floor. In the tobacco factory of Laferme eight cases appeared one day, and on the following day 89 additional cases, only one man in the entire factory remaining free from symptoms. Consideration was given at the time to the possibility of wholesale nicotine poisoning, but strangely enough seven cases appeared in a chocolate factory, then others in a garment factory, in a machine shop, and in other widely separated places of business. Fear was entertained by the populace that the poisoning (?) was due to a political plot. So intense was the excitement that the police suppressed all discussion of the cases and the factories closed their doors until the situation quieted down, so that the ultimate cause of the trouble was not ascertained. Dr. Alice Hamilton, while in Moscow in 1924, made inquiries concerning this outbreak and states that, after all the excitement had passed, investigation established the fact that the toxic substance responsible was benzene. It would seem that this "massenvergiftung" was, for the greater part, in the nature of hysteria, precipitated by a few actual cases of benzene poisoning which occurred in the rubber-making plant.

Adamkiewicz (36) reports a case of accidental acute poisoning in which a workman decended into a pump pit. After three hours he was carried out unconscious, but survived. A strong odor of benzol was present on the breath. Binder (37) cites a fatal case of a man employed in the making of benzol cement. He was overcome by fumes and later died. Cronin (38) reports five cases of posioning,

one being fatal The fatal case was that of a workman who descended into a trench surrounding a large benzol tank, in order to tighten a nut at the site of a leak He grew pale, dizzy, and weak and was forced to rest On reattempting to work he collapsed and died shortly after. Other workers in the same trench complained only of slight dizziness after two hours' exposure Later another workman shoveling earth back into the above mentioned trench became dizzy and collapsed and, on recovery, developed a sense of constriction in the chest, with tremor of extremities, and during the next four weeks had attacks of cardiac distress. Cronin cites three other cases of a spreader, a cement mixer, and a worker in a tank car, respectively, all of whom presented symptoms and signs of headache, dizziness, weakness, etc., which were relieved by going into the fresh air.

Cases of benzol poisoning occurring from the use of paints and lacquers containing this substance are of special interest. From this industry Rambousek (9) cites two interesting cases. In the first instance unconsciousness of a workman resulted from painting a retort with an anticorrosive paint. The accident was attributed to benzol fumes released by the paint in drying. The patient was rescued, given medical attention, and survived. In the second case, a rust-preventing paint with which a workman was painting the interior of a boiler, was the source of the benzol vapors. The paint contained considerable crude benzol, and the worker was overcome while working within a confined space He was quickly resuscitated, but the effects incapacitated him for eight days. Rambousek calls attention to Schaefer's investigation (39) into the question of paints containing benzol At the time (1909), Schaefer emphasized the hazard from benzol in paints, but considered the crude products, boiling between 130°-170° C., as relatively harmless In 1905 6 many of the cases which occurred were attributable to the fumes of hydrocarbons other than benzol, and a case is cited in which a painter was engaged in painting the double bottom of a ship with "black varnish oil." Exposed to the concentrated fumes, he developed severe inflammation of the respiratory system, from which he eventually died. The black varnish oil was a mixture of coal-tar pitch in light coal-tar oil, the oil distilling at 170° C., and amounting to 31-33 per cent of the mixture Schaefer cites other cases occurring in 1908-9. A workman was painting the inside of a boiler with a patented paint and was rendered unconscious Three men going to his rescue were also rendered unconscious. He cites another fatal case due to the use of a patent color which contained 30 to 40 per cent benzol and which was being used within an inclosed space (a chain well). This case proved fatal despite the fact that the worker was allowed out in the open air at frequent intervals.

So far as the pathology of acute benzol poisoning is concerned, probably the earliest autopsy record is that of Sury-Bienz (40) in 1888. The findings in this case consisted of bright red spots on the body; the blood was fluid and dark red Minute hemorrhages were found in pleural and intestinal mucosa. The lungs showed venous congestion, and a reddened condition of the lining of the air passages, which contained blood and mucous In an acute case caused by inhalation of benzol, Beinhauer (41) found the heart-blood fluid, with engorgement of the abdominal vessels and hemorrhages into the gastric mucosa Bloodstained mucus was found in the respiratory passages.

Buchmann (29) describes the autopsy findings in the acute case of a man killed by benzol escaping from a break in a chemical apparatus. Red spots were found on the skin, congestion of the internal organs was present, and minute hemorrhages in the pancreas were observed, though no striking findings were present on microscopical examination, and chemical tests of the organs were found to be negative for benzol. In her article on industrial poisons, Dr Alice Hamilton (5) reports seven fatal cases of benzol poisoning Two of these cases came to autopsy at the hands of Dr. H S. Martland. The main findings as summarized by Doctor Hamilton follow:

Case 1.—Cyanosis (blueness) of the mucous membranes and finger tips, cyanosis of liver, spleen, and kidneys; dilation of the right heart, which was filled with dark fluid blood, pleural ecchymoses (small purple spots, due to hemorrhages under the surface of the tissue) and small areas of acute interstitial emphysema in the lungs.

Case 2—Cyanosis of mouth, lips, and of finger tips; small amount of frothy fluid escaping from the mouth; cyanosis of the brain, heart, liver, and kidneys; petechial hemorrahages (small ecchymoses) in pleura and pericardium, reddened and irritated bronchi On section of the lungs a decided odor of benzene was given off There was an abnormal quantity of phenol in the urine, but not benzene.

In general, the symptoms and signs of acute poisoning by inhalation are faintness, dizziness, excitation, pallor and later flushing, weakness, headache, breathlessness, apprehension of death, tightness in the chest, visual disturbances, tremor, weakness in extremities, rapid pulse, cyanosis, unconsciousness or narcosis, collapse, tremor and convulsions, coma, acute mania or delirium preceding sudden death at times, or in other cases death occurring several hours to several days subsequent to exposure. In extreme concentrations, asphyxiation with death results from respiratory paralysis. When taken by mouth, the usual local signs and symptoms of an acute toxic gastritis are seen in addition to the general systemic manifestations.

In treatment of acute benzol poisoning the patient should, of course, be removed from the danger area and placed in a comfortable reclining

position. If carbon dioxide-oxygen, and respirator are at hand, this means of respiratory stimulation should be at once applied. If only oxygen tank and respirator be available, they may be used; and if no such apparatus be available, artificial respiration by the prone pressure or Schaeffer method should be applied until the patient has been breathing in a satisfactory manner for some minutes. The patient should be carefully watched, and at the first sign of respiratory failure or slowing of respiration the artificial respiration should be resumed. At all times it is important to keep the body warm by applying heat to the body and extremities. Cardiac and respiratory stimulants, such as caffeine, may be given.

In cases where benzol has been taken by mouth, the usual gastric lavage may be resorted to, followed by demulcents or bland drinks. Lecithin emulsion may be administered intravenously, as advocated by Nick, in doses of 5 c.c of a 10 per cent solution.

Prolonged convalescence is essential in order to avoid complications.

Generally, cases of acute poisoning from inhalation are either rapidly fatal or respond favorably to treatment with more or less complete recovery within a short period. Late manifestations may appear, however. Cronin (38) reports spells of cardiac distress for four weeks after recovery. This was true also in Lewin's case, which presented cardiac distress, dizzy spells, and general depression. In the Report of the Chief Inspector of Factories and Workshops of Great Britain for 1918 (42) a case is reported of acute posioning due to too rapid distillation of benzol. The worker was overcome, but was revived and apparently passed through the experience sucessfully. On the second night of his return to work, however, for no apparent reason he lapsed into unconsciousness from which he never recovered. Inflammation of the respiratory tract and pleurisy may set in (43) (39) (9) Pyloric stenosis has been reported after poisoning by swallowing benzene (15). Albuminuria with casts and albumen may occur; also bloody stools (15). It is well to note that in many of the acute cases of poisoning reported, other volatile substances in addition to benzol have been present and probably have contributed to the seriousness of the picture presented. Schaeffer, in 1905–06, called attention to poisoning by the inhalation of other hydrocarbons. Hydrogen sulphide gas is frequently encountered in tar distilleries (9), and more rarely carbonic oxide (44). In many of the quick-drying paints, other solvents present in addition to the benzol probably play a part in the production of acute symptoms, and such symptoms are frequently attributed to benzene. That symptoms of acute benzol poisoning should be rather frequent is not surprising in the light of the findings given by Lehmann, who found that concentrations of 0.015 grams per liter of air (4,700 parts per

million) will produce confusion within half an hour, while concentrations from 0 02 to 0 03 grams per liter (6,160 to 9,190 parts per million) produce definite symptoms of poisoning within a few hours. That the benzol vapor in such concentrations is rapidly taken up is indicated by the fact that 80 per cent of the vapor is absorbed within a short period on exposure to concentrations of 4,700 parts per million From these experiments, however, no definite ratio or proportion could be established between the absolute amount of benzol in the air and the amount absorbed. The signs and symptoms of acute poisoning will therefore depend not only on the concentration present but also upon the susceptibility of the individual and, to a lesser extent, perhaps, upon the activity in which he is engaged.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Typhoid Versus Tourists.—Anon *Ohio Health News*, vol. 2, No. 9, May 1, 1926, pp 1–2 (Abstracted by Isador W. Mendelsohn.)

This article discusses various precautions to be observed by the camper to protect himself against disease, particularly the matter of safe water After two summers' work there are 108 wells in Ohio now bearing the Seal of Safety of the Ohio State Department of Health.

The Engineering Aspects of Oyster Pollution.—R. E. Tarbett, Sanitary Engineer, United States Public Health Service, Washington, D. C, *American Journal of Public Health*, vol 16, No. 1, January, 1926, pp 5–12. (Abstracted by R. E. Tarbett)

The question of oyster pollution is considered in two parts—first, conditions existing in growing areas, and, second, pollution due to insanitary handling, shucking, etc. Patrol over the sanitary conditions of growing and bedding areas appears to be the most important factor in the production of safe oysters. The protection of such areas, however, presents a difficult problem because of the many and varying influences involved

The relation of the *B coli* content of the shell liquor to the overlying water is discussed, with the conclusion that, with the data available, and without considering other data, the determination of the safety of oysters by the *B coli* content of the shell liquor is misleading.

Oysters, being found only in tidal estuaries, are subject to possible polluting influences originating in fresh water streams discharging into those estuaries as well as to polluting influences in the tidal estuaries. Studies of pollution, therefore, involve studies of the streams above tidal influence, and of the tidal estuary or bay itself. These studies involve the estimates of amount of pollution entering the streams, together with the approximate dilution taking place under different conditions of stream flow and probable time interval

elapsing before entry of pollution to the area of tidal influence; they also give information on the amount of pollution discharged to tidal water, together with the action of tides, currents, bottom topography, and the like Lags in tidal currents, vertical stratification, and barrier action of bars interfere greatly with estimates of time intervals and of movements of waters. In addition to the physical considerations, *B. coli* content of the water and of the shellfish should be studied.

Movements of water, effects of dilution, and conditions of pollution may best be studied by the establishment of *B. coli* contours under different conditions of tides and winds.

The handling, shucking, and packing of oysters appears somewhat analogous to the handling of milk, and should be controlled in the same manner in which the handling of milk is controlled.

Chlorination, in respect to oyster purification, should be considered only as an additional safeguard against accidental pollution and not as a substitute for sanitary control over growing areas.

Effect of Storage and Changing Sea Water on Contaminated Oysters.—Charles Krumwiede, William H Park, Georgia Cooper, Marie Grund, Charles H. Tyler, and Carolyn Rosenstein, Bureau of Laboratories, Department of Health, New York City. The *American Journal of Public Health,* vol. 16, No. 3, March, 1926, pp. 263-268. (Abstracted by R. E Tarbett.)

The experiments covered in this article are a continuation of the experiments on the effect of chlorination on oysters contaminated with typhoid bacilli, reported in the February issue of the *American Journal of Public Health.*

The experiments reported on in this article cover the observations of the effect of dry storage and the effect of changing sea water. The oysters in the experiment were obtained from Great South Bay, Long Island, and the water used was obtained from the same bay. Two lots of oysters were contaminated by suspending them in wire crates in tanks containing 8 gallons of contaminated sea water—Lot A, water contaminated by adding a suspension of feces containing *B. typhosus;* Lot B, water contaminated with freshly isolated cultures of *B. typhosus.* The oysters were allowed to drink actively over one night, and were then stored under temperature conditions approximating that of the colder months.

The materials used for examinations were as follows: Washings from the shell, using 10 c. c. of broth per oyster; the shell liquor; and the body of the oyster emulsified in 5 c. c. of broth. Examinations were made at intervals of 1, 5, 7, 9, 10, 14, 21, 28, 35, 41, and 49 days. All the oysters were dead at the end of 41 days. While the number of *B. typhosus* organisms that could be isolated was greatly reduced, positive results were, however, obtained in the shell liquor

and the body emulsion on the forty-ninth day. The shell-washing examination was negative at the end of two weeks in Lot A and five weeks in Lot B. A parallel series of observations on the presence of *B coli* showed that the rate of reduction was somewhat parallel with that of *B. typhosus* Experiments were made to show whether or not a dead oyster was a favorable culture medium for the typhoid bacillus. In oysters contaminated with pure cultures and held at room temperature there was slow multiplication, approximating 15 times, during the first 7 days, with a rapid rise in multiplication to approximately 1,000 times after 10 days In ice-box temperature there was a moderate increase to the seventh day, followed by a decrease, with approximately the original number on the tenth day. Oysters contaminated with stool suspensions held at room temperature were so overgrown with other organisms as to prevent isolation by the direct plating method, but enrichment methods showed *B typhosus* on the tenth day At ice-box temperature this organism was also isolated on the tenth day. Reference is made to results of similar experiments carried on by others.

Fifty oysters were contaminated with typhoid feces and placed in 4 gallons of fresh sea water. This experiment was carried on during a period of 24 days, during which time the water was changed 18 times The temperature of the water was kept between 60° and 70° F. The results indicated that three successive changes of water will give a reduction of about 99 per cent in typhoid bacilli However, at the end of the twenty-fourth day, at which time the oysters were dead, it was possible to isolate the organism from the liquor-body emulsion and its shell.

The length of time that *B. typhosus* will survive in oysters during winter months in natural waters was also investigated. Oysters were obtained from beds in a condemned area and the experiment was carried on in the same area. These oysters were contaminated with a relatively light dose of typhoid feces and submerged in wire crates. The temperature conditions during the experiment were such as to indicate that the oysters were relatively inactive. The results show that the organism was isolated from the liquor up to the tenth day; from the bodies up to the thirty-first day; and from the gills up to the fifty-first day.

It the experiment Endo medium and brilliant green agar were employed, with brilliant green broth used for enrichment. The authors conclude that the only safe oyster is one which has been protected from any contamination with fecal pathogens for at least some months prior to harvesting.

A HEALTH STUDY OF TEN THOUSAND MALE INDUSTRIAL WORKERS

In the near future a bulletin[1] will be issued by the Section of Industrial Hygiene and Sanitation of the United States Public Health Service, entitled "A Health Study of 10,000 Male Industrial Workers."

This study represents the analysis of the physical condition of one of the largest groups of industrial workers yet studied, and includes workers in 10 industries.

Although the original study was made entirely from the viewpoint of industrial hygiene, the publication contains a large amount of basic material of especial value to the physiologist, relating to the blood pressure and pulse rate, vital capacity, measurements of the body and other physiological or physical facts ascertained in routine physical examination.

Of special interest to the physician is the contribution to medical knowledge made by this study regarding the distribution of defects and diseases at different ages. The graphs prepared to bring out these observations suggest the trend of certain diseases throughout the life of the industrial worker, and are also more or less applicable to the general male population of adult ages. This information, which represents a new point of view from which to judge causes of sickness and death, may be regarded as unique in the literature of vital statistics.

DEATHS DURING WEEK ENDED JUNE 19, 1926

Summary of information received by telegraph from industrial insurance companies for week ended June 19, 1926, and corresponding week of 1925 (From the Weekly Health Index, June 24, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended June 19, 1926	Corresponding week 1925
Policies in force	64, 473, 873	60, 266, 214
Number of death claims	12, 127	12, 057
Death claims per 1,000 policies in force, annual rate	9. 8	10. 4

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

Reports for Week Ended June 26, 1926

ALABAMA

	Cases
Cerebrospinal meningitis	1
Chicken pox	10
Diphtheria	5
Influenza	4
Lethargic encephalitis	1
Malaria	49
Measles	167
Mumps	10
Ophthalmia neonatorum	1

PLAGUE-ERADICATIVE MEASURES IN LOS ANGELES, CALIF.

The following items were taken from the reports of plague-eradicative measures from Los Angeles, Calif.:

Week ended June 19, 1926

Number of rats trapped	442
Number of rats found to be plague infected	0
Number of squirrels examined	1,165
Number of squirrels found to be plague infected	0
Number of mice trapped	289
Number of mice found to be plague infected	0

Date of discovery of last plague-infected rodent, Nov. 6, 1925.
Date of last human case, Jan 15, 1925.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria —For the week ended June 12, 1926, 36 States reported 1,083 cases of diphtheria. For the week ended June 13, 1925, the same States reported 1,028 cases of this disease. Ninety-seven cities situated in all parts of the country and having an aggregate population of nearly 29,750,000, reported 785 cases of diphtheria for the week ended June 12, 1926 Last year for the corresponding week they reported 645 cases. The estimated expectancy for these cities was 788 cases The estimated expectancy is based on the experience of the last nine years, excluding epidemics

Measles —Thirty-four States reported 12,985 cases of measles for the week ended June 12, 1926, and 5,603 cases of this disease for the week ended June 13, 1925 Ninety-seven cities reported 4,932 cases of measles for the week this year, and 3,190 cases last year.

Poliomyelitis.—The health officers of 37 States reported 19 cases of poliomyelitis for the week ended June 12, 1926 The same States reported 46 cases for the week ended June 13, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-six States—this year, 2,677 cases; last year, 1,819 cases; 97 cities—this year, 1,460 cases; last year, 934 cases, estimated expectancy, 759 cases.

Smallpox.—For the week ended June 12, 1926, 37 States reported 499 cases of smallpox. Last year for the corresponding week they reported 662 cases. Ninety-seven cities reported smallpox for the week as follows 1926, 95 cases, 1925, 204 cases, estimated expectancy 112 cases. Two deaths from smallpox were reported by these cities for the week this year—at Omaha, Nebr.

Typhoid fever.—Two hundred and seventy-seven cases of typhoid fever were reported for the week ended June 12, 1926, by 36 States. For the corresponding week of 1925, the same States reported 543 cases of this disease. Ninety-seven cities reported 70 cases of typhoid fever for the week this year and 149 cases for the correspond-

ing week last year. The estimated expectancy for these cities was [illegible] cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 91 cities, with a population of more than 29,000,000, as follows. 1926, 585 deaths; 1925, 578.

City reports for week ended June 12, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[1] Rocky Mountain spotted fever, 1 case at Helena, Mont

The following table gives the rates per 100,000 population for 103 cities for the five-week period ending June 12, 1926, compared with those for a like period ended June 13, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 103 cities reporting cases had an

estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926 The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926 The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, May 9 to June 12, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

FOREIGN AND INSULAR

BRAZIL

Yellow fever—Bahia—May 9–22, 1926.—During the two weeks ended May 22, 1926, three cases of yellow fever with two deaths were reported at Bahia, Brazil.

CANADA

Communicable diseases—May 30–June 12, 1926.—The Canadian Ministry of Health reports certain communicable diseases in seven Provinces of Canada for the two weeks from May 30 to June 12, 1926, as follows:

	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever			2	1				3
Influenza	37				2			39
Poliomyelitis				2				2
Smallpox				24	12	7	3	46
Typhoid fever	1	2	16	15	2	2	4	42

Vital statistics—Quebec—February and March, 1926.—Births and deaths in the Province of Quebec for the months of February and March, 1926, have been reported as follows:

	February	March
Estimated population	2,570,000	2,570,000
Births	6,167	7,526
Birth rate per 1,000 population	28.79	35.11
Deaths (all causes)	2,813	3,559
Death rate per 1,000 population	13.13	16.61
Deaths under 1 year	887	1,113
Infant-mortality rate	143.8	147.9
Deaths from—		
Cancer	115	130
Cerebrospinal meningitis	19	11
Diabetes	9	21
Diphtheria	24	26
Heart diseases	323	431
Influenza	135	198
Measles	19	31
Poliomyelitis (infantile paralysis)	1	0
Scarlet fever	9	14
Syphilis	5	7
Tuberculosis (pulmonary)	191	236
Tuberculosis (other forms)		93
Typhoid fever	15	20
Whooping cough	31	38

CHINA

Plague—Amoy—May 1, 1926.—Under date of May 1, 1926, plague was reported prevalent in the city of Amoy, China.

Smallpox—South Manchuria Railway—May 16–22, 1926.—During the week ended May 22, 1926, 18 cases of smallpox were reported at 10 localities on the line of the South Manchuria Railway.

EGYPT

Plague—May 21–27, 1926—Summary—During the week ended May 27, 1926, 4 cases of plague were reported in Egypt, the urban occurrence being 2 cases at Suez. From January 1 to May 27, 1926, a total of 43 cases was reported in Egypt, as compared with 53 cases occurring during the corresponding period of the preceding year.

Later occurrence—Later reports show the occurrence of plague in Egypt as follows: Suez, May 28 to 30, 4 cases with 3 deaths (bubonic and pneumonic); Provinces of Beni-Suef, May 28 to June 3, 5 cases with 2 deaths; and Gharbieh, June 2, 1 case with 1 death (bubonic).

GREECE

Plague—Zante—May 17, 1926.—A press report has been received from Patras, Greece, under date of May 23, 1926, showing the occurrence of a case of plague in the island of Zante, six hours distant from Patras, May 17, 1926.

IRELAND (IRISH FREE STATE)

Typhus fever—Cork County.—A case of typhus fever was reported in the urban district, Cork County, Irish Free State, June 5, 1926.

MALTA

Communicable diseases—April, 1926.—During the month of April, 1926, communicable diseases were reported in the island of Malta as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Broncho-pneumonia	5		Pneumonia	7	
Chicken pox	64		Poliomyelitis	1	
Diphtheria	7	1	Scarlet fever	3	
Erysipelas	6		Trachoma	34	
Influenza	12		Tuberculosis	23	17
Lethargic encephalitis	1		Typhoid fever	15	2
Malta (undulant) fever	48		Whooping cough	20	
Measles	120	1			

Population, estimated, civil, December 31, 1925, 255,242.

MEXICO

Malaria—Tampico—June 1-10, 1926.—During the 10 days ended June 10, 1926, 8 cases of malaria with 3 deaths were reported at Tampico, Mexico.

PERU

Gastroenteritis—Lima—March, 1926.—During the month of March, 1926, 75 deaths from gastroenteritis were reported at Lima, Peru. Population, estimated, 200,000.

SPAIN

Mortality—Madrid—April, 1926.—During the month of April, 1926, 1,333 deaths were reported at Madrid, Spain, as compared with 1,628 deaths in January, 1,248 in February, and 1,584 in March, 1926 Population, estimated, 766,552.

Mortality in children—Of the 1,333 deaths reported in April, 1926, at Madrid, 177 occurred in children under one year of age and 262 in the period one year to four years.

Principal causes of death.—The principal causes of death noted were heart disease with 98 deaths; tuberculosis (pulmonary), 147; pneumonia, 25; bronchitis, 109, other diseases of the respiratory organs, 203. There were 65 deaths from scarlet fever, including 4 deaths from scarlatina and 5 deaths from typhoid fever.

VIRGIN ISLANDS

Communicable diseases—May, 1926.—During the month of May, 1926, communicable diseases were reported in the Virgin Islands of the United States as follows

Island and disease	Cases	Remarks
St Thomas and St John		
Chancroid	3	
Gonorrhea	7	
Syphilis	3	
Tetanus	1	
Tuberculosis	1	Chronic pulmonary.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM
THE SUPERINTENDENT OF DOCUMENTS

HEREDITARY TRANSMISSION OF TULARÆMIA INFECTION BY THE WOOD TICK, *DERMACENTOR ANDERSONI* STILES[1]

By R R PARKER, Special Expert, and R R SPENCER, Surgeon, United States Public Health Service

In May 1924, Parker, Spencer, and Francis[2] submitted data demonstrating the stage to stage transmission of *Bacterium tularense* from larva to adult of the wood tick *Dermacentor andersoni* Stiles. New data, here presented, demonstrate the hereditary transmission of this bacterium from infected female ticks to their progeny

The ticks used in these experiments were part of a lot of laboratory-reared adult ticks, all of them the progeny of one female and free from any demonstrable infection as shown by tests of the antecedent larvae and nymphs and the apparent absence of disease in the hosts upon which they were engorged The strain of tularæmia employed was the same as that used in the previous studies[2] and had been carried in part in ticks and in part by guinea pig transfers since it was secured in May, 1923, from wild adult ticks. The experimental studies were made at the Rocky Mountain Spotted Fever and Tularæmia Laboratory of the United States Public Health Service at Hamilton, Mont

Feeding and infection of parent females.—On May 22, 1924, two Belgian rabbits were each infested with 23 (some male and some female) ticks confined in a brass gauze capsule secured in place by adhesive plaster The rabbits were immediately inoculated by the cutaneous method with spleen tissue of a guinea pig just dead of tularæmia Both hosts were dead of typical tularæmia on May 27, and four engorged female ticks were recovered and put aside. The remaining ticks were at once transferred to two normal rabbits, from which they were removed on June 2, and 11 more engorged females were secured, making a total of 15. The latter two host rabbits died June 13 and 14, respectively, with lesions suggestive of subacute tularæmia. Each of the fed female ticks deposited fertile eggs.

Feeding of resultant larvae, nymphs, and adults.—The 15 lots of larvae were fed, each on a separate Belgian rabbit, at various dates between August 8 and September 15. Five lots failed to engorge;

[1] The experimental studies upon which this paper is based were made in cooperation with the Montana State Board of Entomology

[2] Tularæmia XI. Tularæmia Infection in Ticks of the species *Dermacentor andersoni* Stiles in the Bitterroot Valley, Montana. Pub Health Rep, Vol 39, No 19, May 9, 1924, pp 1057-1073

DISCUSSION

The results of the experiments recorded above demonstrate the hereditary transmission of *Bacterium tularense* in the intermediate host, *Dermacentor andersoni*. Eight of 15 female ticks engorged on infected hosts transmitted infection to their progeny. In two of the eight positive lines of descent, however, infection was recovered only from the eggs and was not demonstrated in the resultant larvae or nymphs.[3] In the other six (in only three of which was egg infection demonstrated) it was recovered from the larvae or nymphs or both. In no one line of descent was it recovered from all three of these stages. Four of the five lots of eggs that gave positive tests caused typical acute infections in the egg-injected guinea pigs. Only one lot of larvae and but one of nymphs, however, caused typical acute death of their hosts. Both were from the same parent. In all other positive tests, tissue transfers from the host animals or from the egg-injected or tick-injected guinea pigs (which were apparently well when killed and autopsied) were necessary in order that the presence or apparent absence of infection might be established.

The results, as stated, suggest (1) That not all infected females transmit infection to their progeny; (2) that the virulence of infection so transmitted may vary in the progeny of different females, even though all were infected from a common source, and (3) that in some lines of descent the infection may die out. The same apparent tendencies have been noted in the much more extensive studies of the virus of Rocky Mountain spotted fever in the same tick species.

The fact that in each line of descent not all stages were shown infective and that many of the positive tests were apparent only after one or more transfers from the initial test guinea pigs indicates the inadvisability of placing undue reliance on apparently negative tests.

The apparent failure to recover infection from the three lots of adults shown to have been infective as nymphs does not necessarily indicate absence of the infectious agent, but even if the agent were absent, the finding would not detract from the significance of the positive results secured with eggs, larvae, and nymphs. The data justify the conclusion that hereditary transmission occurs, but do not warrant any deduction as to the percentage of infected females that thus transmit the bacterium or as to how far it will persist in the subsequent stages. These points doubtless are determined by the conditions attendant upon any particular test.

The hereditary transmission of *Bacterium tularense* by *Dermacentor andersoni* is of interest for two reasons (1) Hereditary transmission

[3] Prior to recorded experiments infection in the eggs had been demonstrated in lots from several females which had been infected as larvae. The tests were not carried further.

of the bacterium assures a greater number of infected ticks in nature than if stage to stage transmission were confined within the limits of a single generation, and it therefore becomes significant as a definite aid in the natural maintenance of infection; (2) although the hereditary transmission of certain protozoa, of some species of rickettsiae and of symbiotic microorganisms by insects or arachnids is a recognized phenomenon, this paper is believed to be the first record of similar transmission of a known bacterium.

THE SUSCEPTIBILITY OF THE COYOTE (*Canis lestes*) TO TULARÆMIA[1]

By R R PARKER, Special Expert, United States Public Health Service, and EDWARD FRANCIS, Surgeon, United States Public Health Service

In June, 1925, Dr J H Garberson, of Miles City, Mont., reported a case of tularæmia, apparently caused by the bite of a coyote (*Canis lestes*). The patient, D S, was bitten on the hand, June 13, by one of five coyote pups which he was removing from their den, close to the Musselshell River, about 2 miles southeast of Melstone Typical onset of tularæmia occurred June 15 A persistent ulcer at the site of the coyote bite and enlarged axillary glands characterized this illness The patient gave no history of tick bite or of having handled rabbits or of any other probable source of infection other than the coyote bite. Blood serum collected from the patient June 27, 1925, and forwarded to the Hygienic Laboratory of the Public Health Service at Washington, D C., was tested by Francis, and found to agglutinate *Bacterium tularense* in all dilutions from 1:10 to 1:640, thus confirming the diagnosis of tularæmia. Numerous rabbit bones were noted near the den, and rabbits seen in the vicinity were sluggish. One of the coyote pups died four days after capture, but the patient did not know whether or not this was the one that had bitten him The remainder of the litter were killed two weeks later.

Because the evidence so strongly favored the coyote as the infecting agency, the question arose whether the bite was infective because of acute tularæmia infection in the coyote itself or because the latter had eaten an infected wild rabbit or other infectious material shortly before biting, the resulting transfer of infection having been purely mechanical The desirability of testing the susceptibility of coyotes was thus suggested. This was made possible by the cooperation of Doctor Garberson, through whom three coyote pups were secured. The experiments were carried on at the Rocky Mountain Spotted Fever and Tularæmia Laboratory of the Public Health Service at Hamilton, Mont.

---

[1] The work upon which this paper is based was performed in cooperation with the Montana State Board of Entomology.

The tests were made by feeding the coyotes the flesh of Belgian rabbits and guinea pigs just dead of acute tularæmia This method of giving infectious material was used because it simulated the most likely natural means by which coyotes might acquire the infection. Rodents, especially rabbits, are an important item in coyote diet, and tularæmia was known to be prevalent among rabbits in the locality in which this case occurred All three coyotes died of acute infection, the specific nature of which was indicated by agglutination tests made before and after the first infective feed, by the occurrence of typical infection in guinea pigs inoculated with tissue obtained at autopsy, and by the recovery from these guinea pigs of pure cultures of *Bacterium tularense* The agglutination and cultural tests were made by Francis, to whom the necessary sera and tissues were forwarded

At the times the tests were begun the coyotes (A, B, and C) were approximately four and one-half, five, and six months old, respectively.

COYOTE A

Blood serum secured from coyote A on July 21 failed in all dilutions to agglutinate *Bacterium tularense*

Between July 29 and August 21 this coyote was fed the spleens and livers of eight Belgian rabbits and five guinea pigs and the entire carcasses of two other guinea pigs. All of these animals had died of acute tularæmia.

Serum drawn August 6 did not agglutinate *Bacterium tularense*. On August 17 it agglutinated in all dilutions up to 1 40; on August 27. in all dilutions up to 1:80, and on September 4, in dilutions of 1:10 and 1 : 20

Death occurred September 20, 53 days after the first infective feed. The carcass was packed in ice and autopsy was made September 21. Parts of the following tissues were emulsified in salt solution and guinea pigs were injected subcutaneously with each, respectively. Salivary glands, axillary glands, inguinal glands, spleen, and lungs. The guinea pig injected with salivary-gland emulsion died September 28, the pigs injected with axillary-gland and spleen emulsions died September 30. Necropsy findings in all three were typical of acute tularæmia. The remaining tests were negative. The infection in the guinea pig injected with salivary-gland emulsion remained typical throughout a series of seven guinea-pig transfers, from one of which a pure culture of *Bacterium tularense* was isolated.

COYOTE B

Serum drawn September 8 did not agglutinate *Bacterium tularense*.

Coyote B was fed the carcasses of four Belgian rabbits dead of typical tularæmia, the carcasses of two being fed on September 9, and of one each on September 11 and 14.

On September 18, nine days after the first infective feed, the serum of this coyote agglutinated *Bacterium tularense* in dilutions up to 1 : 320 and partially at 1 : 640, on September 28 agglutination was positive in all dilutions up to 1 : 320.

Coyote B died October 1, 22 days after this first infective feed. Autopsy was performed immediately after death, but no lesions typical of tularæmia were found. Parts of the following tissues were emulsified in salt solution and guinea pigs were inoculated subcutaneously, with each emulsion, respectively· Salivary glands, axillary glands, inguinal glands, spleen, and liver. The guinea pig inoculated with salivary-gland emulsion died typically on October 10 The lesions remained typical through a series of six guinea-pig transfers, from one of which a pure culture of *Bacterium tularense* was recovered. The other tests were negative.

COYOTE C

Serum of coyote C taken September 4 and again October 13 failed in all dilutions to agglutinate *Bacterium tularense*.

Coyote C was fed one Belgian rabbit on October 18 and two guinea pigs on October 20 and again on October 22, all having just died of typical tularæmia

On October 23 the blood serum failed to agglutinate *Bacterium tularense* in all dilutions; on October 30 it agglutinated in dilutions of 1 : 10, 20, 40, and 80.

The coyote was killed when dying, October 31, 13 days after the first infective feed. No characteristic lesions of tularæmia were found at autopsy. The left prescapular gland showed a condition at one extremity suggestive of beginning abscess formation. Parts of the following tissues were emulsified in salt solution and two groups of guinea pigs were inoculated with each emulsion, one group subcutaneously, the other intraperitoneally. Salivary glands, prescapular glands, axillary and retroscapular glands, inguinal glands, spleen, and liver. Two guinea pigs were also inoculated with heart blood. Only the two inoculated with the emulsion of the prescapular glands showed evidence of infection. Both died typically, one November 5 the other November 8. The lesions remained characteristic in a series of four guinea-pig transfers, from one of which a pure culture of *Bacterium tularense* was secured.

SUMMARY AND DISCUSSION

Three young coyotes, 4 to 6 months of age, were infected with acute tularæmia by feeding them the tissues of Belgian rabbits and guinea pigs just dead of typical infections. Death occurred respectively, 53, 22, and 13 days after the first feed of infectious material. The course of infection in each case was attended by loss of appetite,

and by an increasing weakness and emaciation. At autopsy the tissues showed no gross pathological lesions such as are characteristic of acute tularæmia in laboratory animals. Diagnosis was made by the following findings (*a*) The coyote sera did not show specific agglutinating properties for *Bacterium tularense* before the first feed of infectious material, but did give specific reactions beginning the second week thereafter; (*b*) typical acute tularæmia infection was produced in guinea pigs injected with emulsions of autopsy material from each coyote; and (*c*) pure cultures of *Bacterium tularense* were isolated from the tissues of guinea pigs in which the infection from the coyotes was propagated.

The recovery of typical tularæmia from the salivary glands of two of the experimental coyotes indicates the possibility of human infection by the bite of an infected coyote. Besides the case noted as evidently due to this cause, another case reported by Dr C. T. Pigot, of Roundup, Mont., also in 1925, was apparently infected by the bite of a ground squirrel (*Citellus richardsoni*).

These data are of especial interest as indicating a hitherto unsuspected avenue for the transfer of tularæmia infection from its normal hosts to man; namely, by the bite of a wild rodent or carnivore.

The susceptibility of coyotes and the evident possibility of fatal infection suggest that tularæmia may be a factor, at least, in the diminution of the abundance of coyotes which is so frequently noted following the decimation of rabbit populations in the same localities.

BENZOL POISONING AS AN INDUSTRIAL HAZARD

Review of studies conducted in cooperation with the Subcommittee on Benzol of the Committee on Industrial Poisoning of the National Safety Council

By LEONARD GREENBURG, Associate Sanitary Engineer, Office of Industrial Hygiene and Sanitation, United States Public Health Service

III. PREVIOUS STUDIES OF CHRONIC BENZOL POISONING

Whereas in acute benzol poisoning, the history, the onset, and the course of symptoms lead readily to a diagnosis, in chronic benzol poisoning we find a wholly different picture. The onset is insidious, the early symptoms are generally overlooked, and it is not until the condition becomes relatively grave that it receives medical attention. In 1897, Santesson (45) reported his now famous cases of chronic benzene poisoning. In the tire department of a rubber factory in Upsala, nine young women using benzene cement were taken ill with rather odd symptoms of headache, dizziness, weakness, and hemorrhages of the mucous membranes. Purpuric spots on the skin, bleeding from the nose and gums, vomiting of blood, and bleeding from the vagina were among the more startling features. Various

degrees of anemia were present with the red cell count markedly depressed, in one case down to 600,000 per cubic millimeter, and with the hemoglobin reduced to 20 per cent. Of these cases, four proved fatal within one to four months from the beginning of exposure. Shortly after Santesson's report, Lenoir and Claude (46) reported a fatal case of benzol poisoning in a workman who had been employed for several years in a dyehouse where benzene was used In due time, weakness and loss in weight resulted, then the appearance of bleeding from the nose and gums Later purpuric spots appeared on the skin and the general condition progressively became more grave until the man suddenly died. On autopsy, hemorrhages in the gastric mucosa, in the intestines, and under the endocardium were discovered. Myocardial infarcts were also found. The recognition of the symptoms as a distinct entity due to the effects of benzene, led Oliver (47) to stress the benzene hazard, to outline the general symptomatology of the disease, and to recommend hygienic instructions as to its prevention in industry.

Selling (48), in 1910, was the first to report cases of chronic benzol poisoning in the United States. Of the three cases recorded, two terminated fatally These cases occurred among the workers in the coating room of a tin-can plant in Baltimore, Md. Fourteen young girls were employed in this workroom. Their duties consisted in operating the coating machines, and in handling the tin can ends after a thin layer of rubber dissolved in benzol had been applied to the margin of the can end. In this process, the ends, after emerging from the machine, are still warm, and under such conditions the benzol continues to evaporate into the room air. The concentration of benzol in the air was apparently sufficient to produce fatal poisoning in this case In Selling's report he states that 10 gallons of benzol were used each day, and that the room was provided with excellent natural ventilation, the windows being kept wide open. These facts are interesting in that they suggest the subtle influence of benzol, despite precautions that may be taken to obviate this hazard. The essential features of Selling's cases are as follows:

Case 1—White female, age 14 Doctor Girdwood was treating her mother for pneumonia and his attention was called to the girl by her pallor and the presence of purpuric spots She was feeling well, but shortly after had hemorrhages from the nose and mouth and was advised to enter the hospital She dated the onset of her illness at about a month before admission, when she noticed blue spots on her arms and legs. Shortly after these had appeared, she suffered bleeding from the nose, gums, and throat For the week prior to admission, she had been confined to bed because of weakness and dizziness. No joint pains or gastrointestinal symptoms were present. On examination the patient showed pallor, pale membranes, bluish macules 1–3 mm scattered over arms, legs, and trunk, and bleeding from the gums Ophthalmoscopic examination showed moderate neuro-retinal edema, with pale fundi and great numbers of small hemorrhages The blood count on admission showed red cells 1,090,000 per c. mm. and white blood cells

1,280 per c mm., with 28 per cent of hemoglobin (Sahli) The red cells were smaller than usual and pale and moderate anisocytosis (variation in size of cells) was present Marked leucopenia (deficiency in white blood cells) with a predominance of mononuclear forms was found The platelets were much reduced The girl died eight days after entry The autopsy revealed muscles of a deep red color; blood pale and watery The heart muscle and, to a less extent, the liver, showed fatty degeneration The anatomical diagnosis was purpura hemorrhagica (probably toxic); hemorrhages into the skin, viscera, and serous surfaces Pallor of the organs

Case 2.—White female, age 14 years She complained of spots on body and pain in the side The general history and physical signs were almost identical with those of Case 1. She had been working five months The blood showed 2,100,000 red cells and 560 white cells per c mm, with a preponderance of mononuclears, and hemoglobin 37 per cent The case proved fatal The anatomical diagnosis on autopsy was purpura hemorrhagica, hemorrhages in the skin, viscera, and serous surfaces, pallor of the organs, hyperplasia of the bone marrow, acute pleurisy

Case 3.—Female, age 14, working for three months in the coating room Presented symptoms of anorexia, abdominal pain, vomiting and headache, with fainting spells. Red cells, 4,900,000, W B C, 4,400 per c mm, Hb, 54 per cent This patient recovered and was discharged after six days An examination of the other workers in the coating room revealed four more who had purpuric spots, but they were entirely free from other symptoms

Selling (48) stresses the fact that benzene is a powerful leucotoxin, destroying the white cells of the blood and attacking the entire hematopoietic or blood-forming system in general In 1911 two similar cases (49) were reported of chronic benzene poisoning characterized by purpura hemorrhagica and anemia, and occurring in a rubber works. The same year Glaser (50) reported on an investigation into several cases of benzene-vapor poisoning occurring in a can factory. Fourteen girls were examined and all were found to be anemic. Four had to be removed to a hospital, where one died and one was critically ill. In these cases the presence of anilin and nitrobenzol complicated the picture and was held responsible for the sickness In 1916 McClure (51) emphasized the value of treatment by repeated transfusions and reported a case occurring in the same can factory as that in which the cases reported by Selling occurred. A woman 31 years of age complained of bleeding from the nose and mouth, the appearance of black and blue spots on her body, and also weakness and anorexia. Extreme breathlessness, with anemia, developed later. The red cell count was 1,460,000 and the white cells 1,110 per c. mm.; hemoglobin, 25 per cent. Bleeding time was 14½ minutes. Thirteen successive transfusions were given, and although the first three or four did not produce any definite improvement, the persistent administration of blood led finally to her uneventful recovery and discharge. In his paper McClure also advocates splenectomy in some of the cases of persistent anemia. Numerous other cases of chronic benzene poisoning in can factories are on record. Hogan and

Shrader (52) report three cases of chronic poisoning occurring in young women and resulting in two fatalities As in the previous cases, the workers were engaged in tending the machines in which rubber cement was sprayed around the margin of the can ends. The evaporation of the benzol in the poorly ventilated room was again the cause of the fatalities. The symptoms and signs presented were almost identical with Selling's cases They are briefly presented below

Case 1 —Young girl of 17 years Had been working six weeks in the "dope room" inspecting the tops and bottoms of cans On March 4 she felt weak and had no appetite Later she developed headache and noticed blue spots on her arms and legs On March 14 she experienced difficulty in swallowing food, had a sore mouth, and also spat up blood Examination showed undernourishment, anemia, purpuric spots over arms and legs, stomatitis, and bleeding from the vagina Marked anemia was present. R B C, 1,240 000, W B C, 600 per c mm, Hb 39 Anisocytosis and poikilocytosis were present She was transfused shortly after admission to the hospital, but grew weaker and died

Case 2 —A woman of 25, admitted with a diagnosis of placenta previa. An attempt was made to deliver her and a macerated fetus was obtained Her history is not clear Blood examination showed R B C, 470,000 per c mm; W. B. C., 538 per c mm; Hb 19 per cent

Case 3 —Young girl of 15, employed in a can factory, working on can tops Three days after starting work she had a nosebleed, and a week later hemorrhages from the mucous membranes, loss of appetite, and later persistent bleeding from the vagina Nausea, vomiting, poor sleep, and extreme fatigue were also present. She was admitted to the hospital April 9 On April 12 her blood count showed 880,000 red cells and 950 white cells per c mm, with a preponderance of mononuclear forms. Hb, 16 per cent She was given three transfusions. Immediately favorable response resulted and six days later her blood count showed 2,184,000 red cells and 3,050 white cells per c mm, with 44 per cent hemoglobin The total mononuclear count had decreased from 60 per cent to 48 per cent, and the polynuclear elements had increased from 38 per cent to 50 per cent

These cases emphasize the marked susceptibility of young girls to chronic benzene poisoning and also indicate the rapid onset of grave symptoms Dr. Alice Hamilton (53) cites, from a personal communication, the case of a woman, aged 41, working in a can factory where cans to which covers had been cemented on with a benzol paste were being delivered. Despite downward suction ventilation and a fresh air supply from above, this patient developed headache, nausea, bleeding from the nose and gums, with a rash and purpura over the lower extremities. Her blood count showed 2,512,000 red cells and 2,000 white cells per c. mm. Hemoglobin, 35 per cent. The case proved fatal, although two blood transfusions were given.

Legge (54), in 1918, reported the first known cases of chronic benzol poisoning occurring in Great Britain. Two men were employed in spreading rubber cement on balloon fabric. In September, 1917, the men were transferred to a new spreading room where 20 spreading machines had been installed, but of which only three were in use,

two of them being operated by the men whose cases are under discussion. The composition used was a mixture of rubber dissolved in pure benzol After the lapse of approximately three months there appeared symptoms of malaise and anemia, with subcutaneous and submucous hemorrhages, bleeding from the nose, gums, and bowels The first man stopped work on December 11, 1917, and died December 18, 1917, the second stopped work on December 13, 1917, and at the time of Legge's report he was still seriously ill in hospital An autopsy on the man who died showed submucous hemorrhages in the intestinal tract and under the endothelium of the heart The bone marrow exhibited the characteristic changes of an aplastic anemia. About six months later the remaining worker, who was employed on the third machine, became ill with typical symptoms of chronic benzene poisoning and died The workroom in which these men had been employed was a partitioned area of a larger spreading room. Its dimensions were 12 feet long by 12 feet wide and 11 feet high. It had four windows on one side and two on the other None of the workers in the main spreading room showed any signs of poisoning. Analysis of the air in the partitioned workroom showed benzol concentrations of 210 to 1,050 parts per million by volume, with an average of 550 parts. Doctor Dale, of the Medical Research Committee, advocated the substitution of xylol in place of benzol as the solvent, believing it to be considerably less toxic. Returning to America, we find Harrington (34), in 1917, reporting five cases of chronic poisoning, with three deaths, in the tire-building department of a rubber establishment. Preparatory to vulcanizing, the tires were wiped with a cloth which was moistened with benzol by means of a can so arranged as to deliver a specified amount of benzol on the cloth. This process of moistening the cloth occurred about eighteen times a day. The cases are briefly recorded below

Case 1—Fatal. Male 33 years old Had been in the tire-building department for about a year when his gums started to bleed almost daily. Shortly after this, bluish spots appeared on his body and extremities Nosebleed, extreme weakness, and dyspnea soon appeared and he entered the hospital about five weeks after the onset of symptoms Examination revealed spongy, bleeding gums, pale membranes, slight tremor of head, ecchymotic spots on skin Vertigo and visual disturbances were also evident R B C, 2,288,000, W. B C, 5,000; Hb, 60 per cent. A blood transfusion was given but the symptoms grew progressively worse; delirium and convulsions then appeared, followed shortly by death

Case 2—Fatal Male, 40 years old. Had been working in tire-building department for 11 or 12 months Several months before entering the hospital he became aware of increasing weakness, fatigue, and dyspnea. He began to lose weight, had frequent headaches, and was unable to work continuously He developed uncontrollable nosebleed and finally had to give up work because of the epistaxis, weakness, and dizziness Hospital examination revealed pallor, pale membranes, ulceration and a bleeding spot in the nose, spongy bleeding gums, and ecchymotic spots on the extremities. Palpitation and vertigo were

also present. R B C, 3,400,000, W. B C, 10.000, Hb, 65 per cent Bleeding of the nose was frequent, twitching of head and limbs developed with later paralysis; then delirium, Cheyne-Stokes breathing, and loss of sphincter control appeared, the patient finally lapsing into coma and death

Case 3—Fatal Male, 30 years of age Since 1915 had been working in the tire-building department Late in 1915 he noticed red spots on the face and neck In spring of 1916 he began to feel weak and had headaches and dizzy spells He consulted a physician, whose report disclosed pallor, general weakness, loss in weight, dyspnea, palpitation, weak gait, headache, dizziness, tinnitis, low red and white blood cell counts Two months later he had severe nosebleed with aggravation of all his past symptoms Entered the hospital two weeks later because of uncontrollable nosebleed Evidences of ecchymoses on legs were then present R B C, 2,136,000; W B C, 2,000, Hb, 40 per cent, total mononuclears, 69 per cent, polynuclears, 29 per cent Developed acute lobar pneumonia Autopsy report Acute lobar pneumonia, pulmonary edema, anemia, exhaustion consequent on poisoning by benzol

In addition, Harrington reports several nonfatal cases, one of a tire builder who developed a papular eruption on arms, feet, ears, and neck Blebs then formed, accompanied by fever and itching. This patient stated that 16 or 18 other workers among the 120 employed in that department suffered from similar lesions These local symptoms disappeared on the substitution of naphtha for benzol. In the Bulletin of the New York State Industrial Commission (55) two fatal cases are reported in men who were employed in the coating of fabrikoid with a rubber mixture dissolved in benzol. The benzol fumes escaped from the hot rubber-coated fabric which readily dried as it emerged from the spreader. The symptoms were those typical of chronic benzol poisoning. The first case was that of a man who had been working for about nine months when he noticed that he was bleeding from the gums and had red spots on his legs. Shortly afterwards he had severe nosebleed, which became more frequent. He entered the hospital and died about two weeks later The second man had been working only for about five months. He had not been feeling well and one night he had a severe nosebleed with bleeding from the gums. His temperature rose to 104°F. The symptoms continued until he died. During a subsequent controversy which arose, it was asserted that the company had been negligent in not attempting to remove the fumes, as even before the mishap some complaint had been made regarding the ventilation. It was brought out that the other men in the coating room were subject to relatively frequent nosebleeds, but that still others had been employed in the coating room for 15 years without suffering any bad effects. Tests were made of the room air in the vicinity of the coating machines, and the highest concentration found was less than 5 per cent of benzol.

Newton (56) reports some interesting cases of early poisoning in his study of industrial poisons during the war. He cites the cases of three chemists who were exposed to benzene vapor for periods approx-

imating two weeks The first case, aged 30, had been intensively exposed for about two weeks and complained of headache, loss of appetite, lassitude, and loss of weight Sudden abdominal pain, with nausea and vomiting, developed. Physical examination was negative A leucopenia of 1,200 white cells per c mm was present. He states that the intoxication in this case was largely from inhalation. The condition, including the leucopenia, was entirely cleared up after a month's leave of absence The second case was that of a chemist exposed for about two weeks, who showed a leucopenia of 1,250 white cells per c. mm. but complained of no symptoms Continuing with his work, but with hygienic instructions, the white count rose to 3,200 per c. mm. within a month. The third case was that of a chemist, similarly exposed for about two weeks, who presented a leucopenia of 1,700, with a red cell count of 3,680,000 per c mm. Allowed to continue with his work, but following out hygienic instructions, the blood count at the end of a month showed 3,200 white cells and 4,352,000 red cells per c. mm The above cases are interesting in that they show the early effects of chronic benzol poisoning upon the cell content of the blood, a condition which may exist without the presence of other symptoms, and which suggests a practical and ready means of detecting incipient cases. The chief danger in chronic benzol poisoning arises from the fact that only after serious damage has occurred does the patient realize the gravity of his condition. The institution of periodic blood examination of all employees exposed to benzol fumes, irrespective of concentration or ventilation devices, would go far toward avoiding such hazards.

Flandin and Roberti (57) call attention to a fatal case of purpura in an automobile factory. A young woman had been employed for about two months in a small "hot room," using a solution of rubber dissolved in benzol The room was poorly ventilated, and five other employees were working in it. They were free to take frequent rest periods outside in the fresh air. The patient in question, who was previously well, developed headache, dizziness, and pallor, fatigue, nausea and vomiting; then, later, ecchymoses appeared on the extremities and body, and also bleeding from the membranes. There resulted a progressive anemia, with fever. The blood showed R. B. C. 2,110,000; W B. C. 1,600, Hb. 20 per cent; polynuclears 27 per cent; mononuclears 67 per cent. Death followed within three weeks of the onset of symptoms. Previous to this fatality three other cases of purpura had occurred among the employees of this "hot room," one of the cases proving fatal Starr (58) stresses the importance of detecting the early symptoms of benzol poisoning, emphasizing the fact that the late advanced signs and symptoms usually imply the existence of considerable damage to the organs and tissues and the loss of much valuable time so far as a possible

cure is concerned. He calls attention to a rather unusual outbreak of chronic poisoning. Benzol cement, for economic reasons, is used to some extent in the millinery industry in place of sewing. That the hazard in such use is not negligible is shown by his report. In a millinery establishment a young girl employed as a hat maker presented symptoms of gastralgia, irritation of the upper respiratory passages, headache, and tachycardia upon which a diagnosis of benzol poisoning was based. On inquiry it was found that the girls were employed in brushing benzol cement on buckram hat forms on which they then pressed the cloth or other material to be attached Natural ventilation in the workroom was poor and no means for artificial ventilation were provided The benzol odor was quite distinct, even at some distance from the workers For a while the windows had been closed because of the cool weather prevailing outside, and it was at this time that the chief difficulty arose. The company officials claimed that for the past four years the same brand of cement had been used and that no trouble had arisen. Twenty-two of the 27 girls who actually handled the cement presented definite symptoms of chronic benzol poisoning Two out of four others who did not handle the cement, but who were exposed to the fumes in the room, also gave evidence of being affected. The chief symptoms elicited were "irritation of the mucous membrane of the upper respiratory tract, nausea, vomiting, burning sensation in the epigastrium, frequent urination, giddiness, slight air hunger, and weakness." Starr states that "These symptoms have a tendency to grow worse after the affected person leaves the atmosphere of the factory." Since the cement in this case was only one-third benzol and two-thirds carbon tetrachloride, it is probable that the latter substance contributed to the symptom complex.

Reifschneider (59) also draws attention to the high percentage of workers giving evidence of early symptoms of benzol poisoning. Out of 60 workers employed in the coating room or "dope room," in a can factory, 48 per cent complained of headaches, 36 per cent of dizziness, 16 per cent of pains in the abdomen, 12 per cent of nosebleed. Out of 60, two had red cell counts under 2,000,000, nine had counts under 2,500,000, thirteen had counts between 2.5 and 3.5 million. Reifschneider directs attention to an apparent family characteristic of high susceptibility to benzol. In one family there were three cases, two of which were fatal, while the third had a secondary anemia and was removed before other symptoms developed.

Meda (60) calls attention to the frequency of chronic benzol poisoning in Milan Here many women are employed in the manufacture of raincoats and other rubber goods in which rubber cement is used. He reports three fatal cases occurring in the winter of 1921 among young women who used rubber cement in this work. Four other similar

fatalities occurred in another factory, in addition to several other cases of poisoning which did not prove fatal. Four additional fatal cases occurred in 1922. In this connection Meda cites a case illustrating the particular danger of benzol poisoning in cases complicated by pregnancy. A young married woman had been engaged in raincoat manufacture for seven years without manifesting any untoward symptoms Several months after becoming pregnant, however, definite signs of poisoning rapidly set in with increasing severity. Headache, dizziness, nausea, bleeding gums, and purpura appeared Her delivery was normal, but the symptoms progressed, the red cell count dropping to 600,000 per c. mm., and the white cell count to 1,700 cells. The hemoglobin fell to 15 per cent With careful treatment, however, this patient recovered. Pugliese (61), who studied these cases in Milan, found concentrations of 1,000 parts benzol per million parts of air, and states that serious poisoning may result from concentrations of 200 to 300 parts per million parts of air In the Milan cases Meda calls attention to the apparent spontaneous outbreaks of chronic benzol poisoning which seem to appear more frequently in the winter months and to which young women are peculiarly susceptible He believes that among other predisposing factors, chlorosis, tuberculosis, and pregnancy play a prominent part.

Brucken (62) relates two interesting cases occurring in a rubber factory where girls were employed in cementing rubber balls. One, a girl of 22, had been employed for three years. Headache, dizziness, and weakness developed, while later, blue spots readily appeared on the slightest injury. Frequent and excessive menstruation and an extreme secondary anemia were also present. His other case was that of a young woman, aged 23 years, who had also been employed for about three years. The usual symptoms of chronic poisoning appeared, headache, dizziness, palpitation, bleeding gums, frequent menstruation, blue spots on the arms and legs An advanced anemia was also present. Both cases responded favorably to rest and medical treatment. Faure-Beaulieu and Levy-Bruhl (63) give some interesting neurological findings in the case of a female factory worker who developed malaise, faintness, nausea, palpitation, and general loss of strength. In time nervous symptoms appeared which indicated lesions of the posterior columns and of the pyramidal tracts. The main neurological signs were Increased tendon reflexes, bilateral clonus, positive Babinski, impairment of deep sensitivity, pseudo-tabetic lesions with paresthesias (pain and temperature sense impairment), ataxia and paraplegia, and motor impairment, signs all indicating sclerosis of the dorsal columns and pyramidal tracts. Such lesions were probably due to the combined effects of the prolonged and persistent anemia, and to the possible

effect that the benzol itself might have exercised on the central nervous structure, inasmuch as it has been found that benzol finds special lodgment to excess in these tissues The blood count in this case showed the usual severe secondary anemia and other findings associated with advanced chronic benzol poisoning

Teleky and Weiner (64) give several interesting cases occurring in connection with the manufacture of rubber goods Of 11 cases examined, only 2 were found to be free from any evidences indicating benzol poisoning The symptoms presented were variable—headaches, nausea, eructations, vomiting, tendency to bleed from membranes, irritation of conjunctivæ, and menstrual irregularities being the most frequent The usual secondary anemia with reduced platelets and inversion of the leucocyte-lymphocyte formula were present The substitution of benzine for benzene for a period of eight weeks resulted in considerable alleviation of the symptoms, the definite improvement being marked both objectively and subjectively They emphasize the value of the substitution of other solvents in place of benzol, together with careful medical supervision, believing that blood counts offer a ready means of detecting the early cases Rohner, Baldridge, and Hansmann (65) made a careful study of a case of chronic benzol poison in an effort to correlate the morbid findings described in man and animals exposed to the action of this solvent, and to observe the effects of benzol in chronic myelogenous leukemia. The patient had been exposed to benzol fumes for about three months and presented the typical findings of chronic benzol poisoning. The red cells were reduced to 860,000 and the white cells to 1,400 per c. mm , hemoglobin, 20 per cent The platelets were reduced to 70,000 per c. mm. Autopsy showed numerous hemorrhages into skin membranes and meninges. A bronchopneumonia was present, also focal necrosis of the liver.

Schwenke (66), reporting typical cases of benzol poisoning, concludes that the fumes of crude benzene or the first runnings appear to be more toxic than the purified product.

In addition to chronic cases of poisoning by inhalation, local lesions have been reported from the prolonged handling of compounds containing benzol Carozzi (67), in the results of his inquiry into the Italian printing trade, states that "among linotypists and pressmen we may occasionally observe a peculiar symptomatology, confirmed by the examination of the blood and caused by the continual use of benzol, benzine, mineral oil, and benzographol (pricking, tingling, numbness in the extremities, the number of blood corpuscles is greatly increased)." Vignolo Lutati (68) cites two cases of occupational dermatitis in the interdigital webs of fingers The hands had been frequently wetted in solution of india rubber. Inquiry

showed that a number of other workmen had been obliged to give up work because of similar skin lesions. In Harrington's (34) study of 120 men employed in tire building, a tire builder stated that 16 to 18 men employed in his department had developed lesions similar to his own The worker in question had been employed for two years, but during the last three months a papular eruption had appeared on his arms, feet, ears, and neck. These lesions disappeared when naphtha (presumably petroleum naphtha) was substituted for benzol. Milian (69) also records a case of erythema of the extremities in a worker who handled dyes dissolved in benzene. Simonin (13) noted irritation of the skin, with swelling and itching, in acute poisoning by swallowing Benzene erythema and other cutaneous lesions are relatively frequent in workers handling compounds of benzene. Wolff (70) showed a passing disintegrating effect of benzol on the skin when there is prolonged contact.

In summarizing this review of the literature the following factors should be emphasized in regard to chronic benzol poisoning

Chronic benzol poisoning occurs with greater frequency in cold weather or the winter months when natural ventilation is usually reduced to a minimum by closed windows and doors so that the concentration of the poison in the atmosphere reaches a maximum. Atmospheric conditions of temperature and humidity also play an important part. At times of high heat and high humidity, other things being equal, spontaneous and sporadic outbreaks are most likely to appear. Young girls are especially predisposed to benzol poisoning, as are also pregnant women Conditions of general ill health, tuberculosis, chlorosis, and other conditions lowering the general vitality or interfering with free function of the eliminative organs have a strong predisposing effect The early symptoms comprise headache, dizziness, malaise, loss of appetite, ready fatigue, shortness of breath, and burning of the eyes, throat, and respiratory-membranes Later, nausea and vomiting, with epigastric burning and pain, may appear, and sensations of chilliness and general weakness, with bleeding from the mucous membranes of the nose, mouth, gastro-intestinal tract, and genito-urinary tract. Too frequent menstruation, with prolonged and uncontrollable bleeding from the vagina, is very common About this time petechiae and purpuric hemorrhages may appear on the body and extremities. Burnet (71) regards purpura as a more serious prognostic sign than bleeding from the membranes. Other lesions of the skin may appear in the form of itching erythema, dry scaling, or vesicular papules. Later, complications affecting the central and peripheral nervous system may develop. Various forms of neuritis, with lesions affecting the dorsal column and the pyramidal tracts, may appear, giving rise to pares-

thesias, anasethesias, impaired locomotion, tremor, and trophic disturbances (63) The blood changes are typical

A leucopenia develops in most cases after exposure and increases in severity, although in some cases this is not absolute. The leucopenia may be extreme, reaching almost a complete absence of white blood cells. A reduction in the red cell count then appears, but somewhat later than the leucopenia. The resultant anemia may become extreme, the red cell count being lowered to less than 500,000 per c. mm A corresponding reduction in the hemoglobin occurs to as low as 15 per cent. A considerable reduction in the platelet count appears, especially in the later stages of poisoning. Blood smears present the picture of an aplastic anemia showing but slight changes in the appearance of the red cells Some pallor and anisocytosis are common Almost complete absence of regenerative forms with very few megaloblasts and normoblasts are noted, with scantiness of platelets A marked diminution of the granular types of white blood cells is seen, with a relative increase in the mononuclear forms. The leucotoxic effect is first noticed and is more pronounced on the myelocytic than on the lymphatic elements, so that an inversion of the leucocyte formula results. This gives a relative increase in the lymphocytes and a lowering of the polymorphonuclear forms.

In rapidly developing cases, however, this inversion of the leucocyte formula may not appear, according to Fontana (72). A relative increase in the large mononuclear cells is common Eosinophilia has also been noted in early poisoning, but this disappears rapidly on cessation of exposure (13), (73) The urine may show albumin, fat, casts, hemoglobin, and conjugated sulphobodies. On autopsy the typical findings consist of hemorrhages in the skin, mucous and serous surfaces, and the viscera, pallor of the organs, with muscles of a deep red color. Submucous hemorrhages are found along the gastrointestinal tract, in the pleura, pericardium, endocardium. The marrow of the long bones presents the typical picture of an aplastic anemia.

The treatment in chronic benzol poisoning consists of change of employment in the very early cases, preferably to open-air work, together with the observance of general hygienic measures These early cases generally respond very promptly to treatment. In the severe cases of advanced poisoning in which hemorrhages and anemia have occurred, treatment consists of rest, fresh air, sunshine, iron-containing foods, and the general hygienic measures that are used in combating secondary anemias, tonics, hydrotherapy, ultraviolet ray, etc In advanced anemia with purpura and hemorrhages, McClure emphasizes the value of frequent and repeated blood transfusions. It is well to bear in mind that the anemia and other signs frequently continue and progress for long periods after removal from

exposure, so that carefully adjusted treatment and prolonged convalescence are essential

IV. THE EFFECT OF BENZOL UPON THE BLOOD CELLS AND ITS USE AS A THERAPEUTIC AGENT

The most characteristic pathological effect of benzol is, perhaps, its destructive influence upon the cells of the blood and the blood-forming organs. This effect is so important that it deserves detailed consideration. It seems also desirable to refer to the use of this property of benzol in the treatment of certain diseases characterized by an excess of white blood cells, even at the cost of a slight digression from the subject of industrial benzol poisoning, so that the literature of all phases of the subject may be presented in one place

The typical result of exposure to benzol is a decrease in white blood cells, and this is often followed by a similar reduction in red cells. The first reaction may, however, be an increase in red cells, and, with very minute doses, there may even be an initial increase in the white cell These early increases are undoubtedly due to slight destruction of cells in the circulating blood overbalanced by an increased production of new cells by the cell-forming or hematopoietic organs (the spleen, lymph nodes, and bone marrow). Prolonged dosage or temporary high dosage is always accompanied, however, by damage to these hematopoietic organs themselves and by marked reduction in blood cell content

The temporary stimulating influence of slight amounts of benzol is illustrated by the work of Rabe and Hirshland (74), who found that the administration of minute doses (first to thirtieth decimal dilutions) to men and women produced an increase in white cells (with a decrease in red cells, which seems somewhat anomalous) and an increase in the amount of urine. So, too, Langlois and Desbouis (75) found that exposure to small quantities of benzene fumes in low concentration led to the production of a leucocytosis. There likewise resulted a hyperglobulia, the increase in the red blood cells amounting to as much as 33 per cent above normal. There was, however, no coincident increase in the hemoglobin. Langlois and Desbouis found that within 10 days after exposure the blood returned to its normal state. They also pointed out that these increases in red and white cells were due to an intense hematopoiesis and not to loss of the blood plasma. Similar findings have been noted by other observers (48), (76), (77), (78).

The normal destructive influence of benzol in higher concentration is illustrated by the work of Pappenheim (79), who, by injecting benzol subcutaneously, obtained a leucopenia with a relative decrease in the polymorphonuclear cells, while the lymphocyte count remained more

or less unchanged. The leucopenia occurred in the peripheral blood stream, but in the splanchnic vessels he observed an increase in the leucocyte count. This leucotoxic effect of benzol was made the subject of considerable investigation by Selling (48) (76), who reported three cases of chronic benzol poisoning with two deaths In these cases marked leucopenia and anemia were observed and the autopsy findings consisted primarily of hemorrhages in the skin, mucosa, and mesentery Prolonged studies of the effect of benzol upon the hematopoietic system in animals threw important light upon the degenerating and regenerating influences affecting the entire hematopoietic system. From these animal experiments Selling emphasized the leucotoxic action of benzol, which not only destroyed the white cells in circulation but extended its destructive influence to the entire hematopoietic system, the bone marrow, lymph nodes, and spleen, and also led to fatty degeneration of the other organs. The leucopenia he found to affect the polymorphonuclear cells to a considerably greater extent than the lymphocytes, and, similarly, the myelocytic structures more than the lymphadenoid. Little direct effect was noted in the circulating red cells, however. In addition to the anemia, pallor and some anisocytosis were present, but no poikilocytosis. Autopsy revealed processes amounting to almost complete aplasia in the bone marrow, this aplasia affecting all the cell types. In the spleen a destruction of the parenchymal elements leading to an aplasia was noted, the aplasia affecting the cells of both the malpighian corpuscles and the pulp strands. Fontana (72), in his experimental work, noted a diminution in the volume of the spleen in rabbits poisoned with benzol. Similar destruction was noted in the follicles of the lymph glands. Of the other organs the liver and kidney showed varying grades of fatty degeneration, and hemorrhages were present in the serous and mucous surfaces. Selling noted that if the benzol injections were discontinued in time, active regeneration occurred in the organs and islands of blood-forming cells developed in the marrow. In the spleen active myeloid-metaplasia occurred and islands of myelocytic and erythroblastic tissue developed in addition to the usual splenic structures. Similar findings have been noted by other workers (72) (78) (104)

Weiskotten (78) and his colleagues call attention to a marked initial fall in the absolute number of both amphophiles and small mononuclears. This preliminary fall is followed by a primary rise in the leucocyte count, which he shows to be due mainly to an increase in the amphophiles. This is the phenomena observed by Rabe and Hirshland and Langlois and Desbouis. This primary rise is followed by a secondary drop in the white cell count, which again is due mainly to a drop in the amphophilic cells, the small mononuclear cells playing

but a secondary rôle in either the increase or decrease. The amphophilic curve follows closely that of the total white cell curve, and toward the end of the experiment, when benzol has been discontinued, the total white count assumes a new level which is generally somewhat lower than the original normal level. This lowered new level is again due in part to the failure of the small mononuclears to rise to the point existing before the beginning of injections, whereas the polynuclear cells do approximate the original level (80). In benzene inhalation experiments similar results were obtained, but no diphasic leucopenia was observed (103) In their study of the red cell reduction, Weiskotten and Steensland (80) found that the compensatory metaplasia in the spleen was of slight significance and that this organ played an insignificant rôle in either the destruction or regeneration of the red or the white cells following benzol poisoning. A relative eosinophilia has been noted in acute and early chronic poisoning, but this rapidly disappears on removal from exposure (13) (73). Duke (81), experimenting with rabbits, obtained an initial rise in the platelet count up to 1,780,000, but this was followed by a rapid fall to a value as low as 61,000. Hurwitz and Drinker (82) found that the platelet count might remain high with a low white cell count, and in the light of their bone marrow findings they suggested that this indicated either very rapid regeneration of the megacaryocytes (the origin of platelets) or a greater resistance of the megacaryocyte to the action of benzol. Weiskotten and his colleagues (83) noted a similar temporary increase in the platelets or thrombocytes, but this increase was in all cases followed by a gradual fall.

Study of the bone-marrow sections showed that as active necrosis developed in the bone marrow, the thrombocyte curve fell; but as regeneration of the marrow set in, active thrombocytosis appeared, with an abrupt rise in the thrombocyte count Sections of bone marrow at the beginning of this thrombocytosis showed large numbers of megacaryocytes in the regenerating marrow, this seeming to indicate that thrombocytes originate in this tissue. Similar decreases in the platelet count have been noted by other observers (48) (72). When the reduction in the platelet count becomes extreme, purpura hemorrhagica, with hemorrhages from the membranes, may take place. Associated with the decreased platelet count, Hurwitz and Drinker (82) have noted a reduction in the circulating prothrombin, but only in one case could they lower the platelets sufficiently to reproduce symptoms of hemorrhagic disease. Duke (81) noted prolonged bleeding time in benzol poisoning, but this occurred only when the platelets fell to a dangerously low level. Forbes and Hompe (84), exposing cats to an atmosphere of benzol vapor sufficient to keep them unconscious, found no constant change in the coagulation time or in the prothrombin content. No hemorrhages were found after five

hours' exposure and no evidence of hemolysis was present, and the urine was never dark or cloudy It would seem that the changes in the bleeding and coagulation time are not so likely to appear in acute poisoning as in chronic poisoning, a fact which probably explains the lack in uniformity of results obtained by Forbes and Hompe. McClure (51) observed greatly prolonged bleeding time in his cases, as have also most other observers in either animal experiments or in clinical observation.

The unfavorable influence of benzol upon the blood cells has led to further important research into its effect upon the general serological and immunological aspects of the blood. Winternitz and Hirschfelder (85), working on experimental pneumonia in rabbits, found that the resistance of these animals was strikingly reduced after they had been given benzol injections sufficient to produce a leucopenia. The animals were rendered leucopenic by benzol administration, and intratracheal insufflations of virulent pneumococci in graded doses were then administered It was found that the resistance of the animals so treated was markedly reduced, so much so that they all died within 13 to 27 hours after injection, while in the control animals not treated with benzol the average interval preceding death was 61 hours It was also found that the cells of the exudate in the lungs were characteristic and proportional to the type and the number of cells found in the bone marrow at the time of death. Besides the usual cell elements, the exudate included such rare forms as megacaryocytes and granulocytes corresponding to the types found in the marrow. Kline and Winternitz (86) further emphasize the lowering of resistance that accompanies such leucopenia. Animals suffering from leucopenia caused by benzol readily succumb, while animals treated with injections of toluol (homologue of benzene which produces a leucocytosis) not only have normal resistance but exhibit an increase in resistance proportional in some degree to the leucocytosis produced. They note, moreover, that the blood count is not always a safe index of bone marrow activity. Weiskotten and Steensland (87), in studying the effect of benzol upon rabbits, noted that evidences of active acute infection frequently appeared which were not present prior to the injections. They suggest that benzol administration by lowering the resistance may stir up latent or quiescent infection In three out of the four animals developing spontaneous infections after benzol treatment, there was absence of the typical bone marrow aplasia, and they conclude that the white cell count is not an absolutely safe guide in the therapeutic administration of benzol. Similar observations had been made by other observers

Weiskotten, Schwartz, and Steensland (88) have noted that the interval between the first injection of benzol and the onset of the deuterophase (secondary decline in the number of white blood cells)

varied between 8 and 13 days. This corresponds closely with the period required for sensitization after injection of antigens. By subjecting rabbits to successive sets of injections the investigators found that there occurred no changes in the deuterophase, suggesting that it was attributable to an antigen-antibody reaction. Schiff (89) demonstrated, however, that small doses of benzol increased the anaphylactic reaction of guinea pigs sensitized to sheep serum, while large doses decrease their sensitiveness.

Hektoen (90), using defibrinated sheep blood as antigen found a marked reduction in the formation of percipitins and hemolysins and in phagocytic power in rabbits which had been treated with benzol. In some animals he found almost an entire suppression of these immune bodies Together with these findings there appeared the usual picture of leucopenia and injury to the hematopoietic apparatus. Rusk (91) likewise found a similar depression in the production of hemolysins and precipitins when animals had been treated with benzol. Simonds and Jones (92) using washed dog blood corpuscles, as antigen, made a study of the hemolytic titer in rabbits previously treated with subcutaneous injections of benzol. They found that the titer of the serum in the benzol-treated animals ranged from one-sixteenth to one-quarter that of control animals Using killed cultures of *B. typhosus* as antigen they found a marked decrease in the production of agglutinins, but to a lesser extent than in the hemolysins. Using typhoid bacilli, they found a markedly reduced power to produce opsonins, but this was noted to a still lesser extent than either the reduction in the agglutinins or hemolysins. White and Gammon (93) noted that rabbits which had been treated with benzol inhalation were considerably less resistant to tuberculous infection than animals not so treated, and Camp and Baumgartner (94), in their study of the inflammatory reactions in rabbits treated with benzol, found that little resistance was offered to the entrance and growth of bacteria in such animals.

It appears from the foregoing that, apart from variation and individual susceptibility and the effect of atmospheric conditions, such as heat, etc., all of which may modify the benzol hazard in any particular case, there may also result in benzol poisoning a depression in the fundamental defense mechanisms of the blood which markedly lowers resistance to other disease processes, all of which considerations contribute still more to our realization of the seriousness of the benzol hazard.

Suprisingly little has been done in regard to the ultimate fate of benzol in the body. It would appear from the work already reported, however, that a considerable portion of the absorbed benzol is excreted in an unchanged condition through the lungs. Juvalta (95), on feeding phthalic acid, found that the benzene ring was broken down

in the animal body. Jaffe (96), in experiments upon dogs and rabbits, noted that, following the prolonged administration of benzene, very small quantities of an N-free acid were present in the urine. The formula was determined to be $C_6H_6O_4$, an oxidation product of benzol, and was found to be identical with muconic acid. This represented, however, but a minute fraction of the total benzene administered. Fuchs and Soos (97) confirmed the work of Jaffe. Sohn (98) found that benzene influenced the oxidative or katabolic processes in the organism, as was shown by an increase in neutral sulphur and changes in the amount of urea and NH_3. Albuminuria also appeared. Brewer and Weiskotten (99) made daily determinations of the phenol content of the urine of rabbits prior to and subsequent to daily injections of benzol, the determinations extending throughout the entire cycle of the leucocyte curve. They found that the phenol content of the urine increased during the prophase, or initial drop in the white cell count, but that no increase in the phenol content occurred during the deutrophase, or secondary drop in the count They conclude from this that the secondary drop in the leucocyte curve is not the result of slow or of delayed absorption of the benzol, as was suggested by Selling (76). Underhill and Harris (100), studying the influence of benzol upon metabolism found a marked increase in creatine output within 48 hours after injection of the substance. This was shortly followed by a sharp fall in the creatine output, but a secondary rise in the excretion appeared still later. There was a less marked increase in the output of total nitrogen, and the total nitrogen elimination curve followed closely that of the elimination of creatine although the total nitrogen was not increased to so great an extent as the creatine. They conclude that benzol exerts a marked catabolic influence on the body structures as a whole

V. THE EXTENT OF THE BENZOL HAZARD IN INDUSTRY IN THE UNITED STATES

Passing from the review of the existing literature of benzol poisoning first of all will be considered the evidence obtained in regard to the seriousness of the problem as it exists in industry in the United States at the present day.

In order to throw light upon this general question, and also to obtain information as to the localities where more intensive studies could profitably be undertaken, a preliminary list was prepared of 324 industrial establishments which, from the nature of their products, might be expected to use benzol. Through the courtesy of Mr. W S. Paine, of the Aetna Life Insurance Co., the following questionnaire was forwarded to all of the 324 industrial establishments in July, 1923.

PRELIMINARY QUESTIONNAIRE FOR BENZOL STUDY

1 Is benzol used or produced in any of the processes in your plant?
If so, would you be willing to give some information as to the extent to which it is used and the amounts employed?
2 How many of your employees are in processes where benzol is present?
(a) Fumes
(b) Liquid
3. How many are directly exposed to benzol?
(a) Fumes
(b) Liquid
4. Have you experienced definite cases of poisoning?
5 Have you considered benzol poisoning as a cause of illness, absenteeism, or labor turnover among your employees on account of any special type of sickness, for example—
(a) Anemia, purpura, hemorrhages, gastro-intestinal or nervous disturbances, neurasthenia, disturbance of menstrual function in women workers, or
(b) Sudden cases of collapse, shock, cyanosis or heart failure.
6. What precautions are you taking to eliminate hazard from benzol poisoning?
(a) Fumes
(b) Liquid
Name of firm: --
Address --
Please forward to:

One hundred and forty replies were received in answer to this questionnaire. Fifty-six of those who answered replied that they did not use benzol in any form, leaving 84 firms who did make use of this substance Some idea as to the amount of benzol used by the firms replying to the questionnaire may be gained from the following figures. Thirty-six replies gave no definite information in regard to this point; in 19 cases the amount of benzol used was insignificant; in 6 cases it was between 5 and 25 gallons per week, in 4 cases between 26 and 99 gallons; in 10 cases between 100 and 500 gallons; in 3 cases between 501 and 999 gallons; in 6 cases over 1,000 gallons—reaching the very high figures of 2,200, 3,000, 7,500, 8,000, 10,000, and 30,000 gallons per week, respectively. The six largest users included three rubber companies (8, 23, and 25) and three large chemical concerns (13, 24, and 19), one of the latter being principally concerned with the supply of products for the making of can seals. It is interesting to note that out of 15 companies reporting cases of benzol poisoning, only 2 were among those using less than 100 gallons of benzol per week; 4 were among those using between 100 and 1,000 gallons; 3 were among the 6 firms using over 1,000 gallons; while 6 were among the 36 firms giving no information as to the amount of benzol used.

A more helpful analysis from our standpoint deals with the number of employees exposed to possible toxic effects of the benzol. We have this information reported for 67 firms, 73 industries having

failed to state the number of employees exposed in processes where benzol constitutes a hazard. The general results are indicated in the table below, with comparative figures showing the number of firms in each class which reported having had cases of benzol poisoning.

TABLE 1

	Number of employees exposed to possible benzol poisoning						
	0-4	5-9	10-24	25-49	50-99	100 and over	No information
Number of establishments in each class	30	14	10	7	2	4	73
Number of establishments reporting cases of poisoning	3	1	3	3	1	4	-- -----

Out of 23 establishments with 10 or more employees exposed to benzol poisoning, 8 were rubber factories, 5 were chemical works, 4 were paint and varnish makers, 3 were gas plants making benzol as a by-product, and 3 were plants of other types.

It will be noted that out of 44 establishments with less than 10 employees exposed to benzol poisoning only 4 reported having experienced cases of poisoning Of 17 firms with from 10 to 49 employees exposed, 6 had experienced cases of poisoning, while of the 6 firms with more than 50 persons exposed to benzol all but one had experienced industrial poisoning by benzol. It is of course possible that facilities for the diagnosis of benzol poisoning may influence data such as Table 1 presents, and that full-time physicians in large industries may naturally be expected to diagnose cases of industrial poisoning more frequently than persons who are not familiar with the symptoms of such conditions.

Table 2 presents the more important data with regard to 33 individual industries whose reports seemed of special interest for one reason or another The table includes (*a*) all plants reporting cases of benzol poisoning, (*b*) all plants reporting the exposure of 10 or more employees to the possibility of benzol poisoning and (*c*) all plants reporting the use of 500 or more gallons of benzol per week. The plants are arranged in order according to the number of employees exposed to benzol and are identified by arbitrary key numbers, since the information obtained in this study was in many cases of a confidential nature

TABLE 2.—*Data with regard to establishments where benzol hazard may exist*

Key Number	Product	Gallons of benzol used per week	Number employees exposed	Poisoning cases	General precautionary measures used
8	Rubber goods	2,200	1,080	Yes	Ventilation
21	do		150	Yes	Do
9	Chemicals	525	100	Yes	Closed containers, ventilation
15	do		100	Yes	Closed apparatus, ventilation, helmets partial elimination of benzol
5	Rubber goods	100	50	Yes	Ventilation, medical examination
26	Celluloid, leather, cloth		50	Yes	Local ventilation, medical examination
27	Japanned goods	60	35	No	Ventilation.
6	Gas by-products	500	32	Yes	
25	Rubber goods	7,500		No	Closed containers, ventilation.
23	do	8,000	30	Yes	Do
28	do		25	No	Limiting use of benzol
29	Chemicals		25	No	
17	do		25	Yes	Closed containers, ventilation
30	Rubber goods	25	25	No	
31	Gas by-products		20	No	Closed containers
38	Paints and varnishes		20	No	Ventilation, closed containers
32	Cans		18	No	Local ventilation
11	Paints, varnishes		15	Yes	Respirators
33	Gas by-products		13	No	Closed containers, ventilation
20	Rubber goods	25	12	Yes	Local ventilation, rubber gloves
22	Vegetable oils		12	Yes	Medical examination, education
34	Chemicals		10	No	Closed containers, ventilation
35	Paints, varnish	250	10	No	Education
10	Chemicals		10	No	Closed containers, care in cleaning tanks.
19	Can solvents	10,000	8	Yes	Ventilation
24	Chemicals	30,000	7	No	
36	do	750	4	No	Closed containers, ventilation
37	Benzol used in cutting asphalt	700	4	No	Closed containers, low temperatures
13	Chemicals	3,000	4	No	Closed containers
12	Paints, varnish	150	3	Yes	Change of employment
7	Rubber goods	5	3	Yes	Ventilation, limitation of use of benzol

The result of this preliminary study was to indicate that the industrial firms using benzol were generally alive to the dangers involved and had in most cases taken definite precautions for the protection of their employees. Nevertheless out of 23 establishments in which 10 or more persons were exposed to benzol, 11, or nearly one-half, reported cases of poisoning, while of 6 plants in which 50 or more employees were exposed, all but 1 reported poisoning.

During the second year of the investigation many additional reports of benzol poisoning were obtained in those plants which were studied more intensively, and the net results of the questionnaire and the field study are presented in Table 3.

TABLE 3.—*Deaths and illness due to the use of benzol in industry, 1922–1924*

Plant No.	Accidental exposure to heavy concentrations		Habitual exposure to lower concentrations		Plant No	Accidental exposure to heavy concentrations		Habitual exposure to lower concentrations	
	Deaths	Illnesses	Deaths	Illnesses		Deaths	Illnesses	Deaths	Illnesses

16				1	83				1
17		1		1	93				7
20				2	95				2
23				2					
27				2	Total	4	2	11	81

In the period going back for several years prior to 1925 the necessarily very incomplete data of this survey thus revealed 15 fatalities and 83 cases of sickness due to benzol, a record of considerable significance It is generally accepted that reports to the various State health departments understate the real situation with regard to industrial disease, and yet in the State of Ohio 29 compensable cases of benzol poisoning occurred during the five-year period ending June 30, 1925 (101) During the last year of our work no attempt was made at a further canvass of new cases; but at lest seven fatalities resulting from benzol poisoning were brought to the attention of the committee as occurring during the first nine months of 1925.

The subsequent portions of this report deal with the committee's studies of chronic benzol poisoning in some detail. It may, however, be well briefly to describe here some of the acute cases of poisoning, which have come directly or indirectly to the attention of the committee during the progress of the work

Plant No 6. A worker operating a benzol still was overcome by fumes when the distilling process started too rapidly and the rectifying chamber ran over.

Plant 67 An employee working in a trench to repair a leak in a pipe containing benzol was overcome by the vapors. He recovered in a few minutes and returned to work He collapsed a second time and died without regaining consciousness.

Plant 48. In this plant, benzol was used in a chemical process. The process depended on volatilizing the benzol, and leaks have frequently occurred The release of vapors due to these leaks resulted in the death of two workmen who were attempting to shut off the system. Recently a leak permitted such a great quantity of fumes to escape that they traveled around a fire wall, became ignited, and burned up the plant Apparently the exhaust ventilating ducts which were of fairly large size did not check the fire hazard or save the workmen from poisoning in this case.

Benzol was used as the solvent in the grease-extraction process at a garbage-reduction plant. The tank containing the benzol was supported on several masonry supporting-walls which, with the tank bottom, formed a closed pocket. This tank was found to be leaking and the workman who went under the tank into this inclosure was killed while looking for the leak.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Cities Notify Public of Water Purity. Regulations Promulgated by the State Department of Health of Minnesota. Anon. *Water Works Engineering*, vol 79, No. 6, March 15, 1926, pp. 323 324. (Abstract by H B Foote.)

In this article the regulations governing the posting of signs notifying the public of the approval of the public water supply are set forth. Fees required for the inspection and analysis of the water followed by the approval of the sign posting are given. These fees are annual and are set at the following figures

Population of municipality	Fee for each separate water-supply investigation
Under 1,000	$15 00
1,000 to 5,000	20 00
5,000 to 20,000	25 00
20,000 to 100,000	35 00
Over 100,000	50.00

Any extra investigations over the annual one must be paid for at the same rate as set forth.

Two official signs are given; each is 18 by 24 inches and should be of metal. The signs must be removed if for any reason the municipality fails to comply with the regulations and any recommendations set forth by the State board of health. It is optional with the city whether it shall come under this ruling or not, but no city shall post signs unless it has complied with all requirements

Chlorination of Water and Sewage. Earle B Phelps *Journal Boston Society of Civil Engineers*, vol. 13, No. 4, April, 1926, pp. 150–167. (Abstract by E C. Sullivan.)

This paper discusses chlorination in the light of the developments of the past 16 years. Inquiry is made into the principle and chemical basis of disinfection, the legitimate and proper rôle of chlorination in water supply practice, and the accomplishment and possibly some of the shortcomings of the process itself. It is estimated that not less than 30,000,000 people in the United States, living in some 3,000 communities, are to-day supplied with a chlorinated domestic water.

When calcium hypochlorite was first applied to drinking water, through fear that the addition of the chemical substance would lead to public disapproval the solution of hypochlorite was referred to as "potential oxygen" in an attempt to disguise the true nature of the treatment, based upon the theory that chlorine acted solely as an oxidizing agent. Later investigations have shown the oxidation theory to be untenable and that in comparison with other oxidizing agents the relative germicidal power of chlorine is much greater than

its relative oxidizing power. The view is now fairly established that the germicidal action of chlorine is a specific toxic action similar in its general effects to the action of phenol, copper sulphate, and other nonoxidizing germicides. It is pointed out that chlorine is in no sense a suitable reagent for oxidation of organic matter in general.

At the time when chlorination was first introduced it was felt that there was grave danger that this new process might be too readily accepted as a substitute for more thorough measures of water and sewage treatment. For once in the history of sanitation there was an actual danger that a sanitary achievement of real merit might be too readily accepted, for the cheapness and simplicity of the process threatened to bring about a condition of unsound practice which might discredit the process itself.

During the past 16 years the process of chlorination has become almost universal in water-works practice It has not only been very generally adopted in the case of slightly polluted waters, but has also been used as an adjunct to filtration processes of all sorts This development has permitted the use of higher loading factors upon filters, and has also, in many cases, provided a wide margin of safety between a badly polluted water and the consumer There is considerable discussion at the present time of the propriety of the use of chlorination alone in the treatment of moderately polluted water supplies Chlorination is an ideal method that provides a wide margin of safety at a low cost when superimposed as an independent process upon the usual treatment by filtration. However, in most cases where filtration is followed by chlorination somewhat greater reliance is placed upon the latter. Thus, chlorination becomes part of the major process and the margin of safety is narrowed. It is a matter of judgment just how far the "margin of safety" purpose of chlorination may safely be encroached upon in order to economize in capital and operating expenditures. It is not the matter of filtered or unfiltered waters that determines the limits of chlorination, but rather the quality of the water with which chlorination must deal. Exactly the same conditions prevail in the chlorination of raw water or waters not otherwise treated.

The writer also discusses the general reliability of chlorination processes as measured by the possibility and effects of mechanical failure; the reliability of control methods for regulating the dosage. the germicidal efficiency as affected by variable water conditions; and other similar matters. The desirability of duplicate apparatus is pointed out. The control of the dosage by the orthotolidine test is discussed. In each type and condition of water there is a certain relation between chlorine dosage, bacterial efficiency, and residual chlorine after a given lapse of time. When the test is properly standardized for a given water it becomes a valuable and almost indispensable guide

to proper dosage. The significance of "aftergrowths" is likewise touched upon. They should be looked upon with suspicion until their status in each case has been more fully determined.

The results of chlorination are discussed to considerable extent, data for a number of cities being cited. The author mentions that the gross treatment of statistical data in comparative typhoid fever rates before and after chlorination has often lead to erroneous conclusions. Suggestions are made for the proper handling of such data.

Tastes and odors are discussed briefly. For phenol wastes there seems to be no remedy except to keep the offending wastes out of the river. Mention is made of a slightly higher rate of dosage to overcome taste and odor troubles resulting from the chlorination of a water supply rich in organic matter

The chlorination of swimming pools and also of sewage is discussed In the usual sewage treatment processes bacterial removal is but incidental to the primary purpose of these oxidation processes. Chlorination possesses great merit for efficiency and economy in producing a reasonably disinfected effluent. Its use will be more frequently employed in the future as its merits become better understood and as need for better protection of inland and coastal waters becomes more manifest. The specific action of chlorine as a toxic agent in distinction from its action as an oxidizing agent is a general principle of chlorination, best illustrated in sewage practice.

Typhoid Epidemic from Deep Well, Polluted by Surface Seepage. R. O. Heater. *Water Works Engineering,* vol 79, No. 5, March 1, 1926, p. 272. (Abstract by F. C Dugan)

In drilling a well a small stream of water was encountered at about 155 feet, or about one-half the total depth, but it was not cased off. Ten years afterwards, due to a typhoid outbreak, it was discovered that water from an abandoned rock quarry was evidently seeping into this small stream. It was cased off and the water supply has not shown any contamination since.

Pure Water—No Typhoid. Anon. *Ohio Health News,* Ohio Department of Health, vol. 2, No. 5, March 1, 1926, pp. 3–4. (Abstract by Isador W. Mendelsohn.)

East Liverpool, Ohio, procures its water supply from the Ohio River at a point only 44 miles below Pittsburgh. The effect of the installation of a modern water-purification plant upon the typhoid incidence in the city is shown in the accompanying table, the factor of improvement in quality of milk being also responsible for the favorable data.

Data on typhoid fever at East Liverpool

Year	Population	Deaths from all causes, children under 5 years		Deaths from typhoid fever, all persons	
		Total	Rate [1]	Total	Rate [1]
1915	20,900	92	341	16	75.8
1916	21,000	125	600	15	71.4
1917	21,100	124	683	15	71.1
1918 [2]	21,200	115	540	18	84.9

Determining Chemical Dosage for River Water. K. C. Armstrong, assistant chemist, Metropolitan Utilities District of Omaha, Nebr., *Water Works Engineering*, vol 79, No. 5, March 1, 1926, pp. 267–268 and 292 (Abstract by F. C. Dugan.)

Variations in pumpage and changes in turbidity constitute a problem in determining the proper chemical dosage for the sedimentation system of the Omaha water supply. A rather unique apparatus for determining the amounts of coagulant necessary is described. The article shows what can be accomplished in the reduction of chemicals by proper laboratory control.

DEATHS DURING WEEK ENDED JUNE 26, 1926

Summary of information received by telegraph from industrial insurance companies for week ended June 26, 1926, and corresponding week of 1925. (From the Weekly Health Index, July 1, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended June 26, 1926	Corresponding week, 1925
Policies in force	64,836,039	60,370,192
Number of death claims	12,056	11,123
Death claims per 1,000 policies in force, annual rate	9.7	9.6

Deaths from all causes in certain large cities of the United States during the week ended June 26, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, July 1, 1926, issued by the Bureau of the Census, Department of Commerce)

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended June 19, 1926, 36 States reported 871 cases of diphtheria. For the week ended June 20, 1925, the same States reported 972 cases of this disease. One hundred cities, situated in all parts of the country and having an aggregate population of more than 30,300,000, reported 656 cases of diphtheria for the week ended June 19, 1926 Last year for the corresponding week they reported 651 cases. The estimated expectancy for these cities was 784 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-three States reported 10,314 cases of measles for the week ended June 19, 1926, and 4,183 cases of this disease for the week ended June 20, 1925. One hundred cities reported 4,257 cases of measles for the week this year and 2,390 cases last year.

Poliomyelitis.—The health officers of 36 States reported 19 cases of poliomyelitis for the week ended June 19, 1926. The same States reported 44 cases for the week ended June 20, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-six States—this year, 2,434 cases; last year, 1,639 cases; 100 cities—this year, 1,356 cases, last year, 910 cases; estimated expectancy, 672 cases.

Smallpox.—For the week ended June 19, 1926, 36 States reported 346 cases of smallpox. Last year for the corresponding week they reported 603 cases. One hundred cities reported smallpox for the week as follows. 1926, 65 cases; 1925, 193 cases; estimated expectancy, 92 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Three hundred and thirty-six cases of typhoid fever were reported for the week ended June 19, 1926, by 35 States. For the corresponding week of 1925 the same States reported 597 cases of this disease. One hundred cities reported 65 cases of typhoid fever for the week this year and 123 cases for the corresponding week last year. The estimated expectancy for these cities was 90 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 95 cities, with a population of more than 29,700,000, as follows: 1926, 538 deaths; 1925, 472.

City reports for week ended June 19, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[2] Dengue, 2 cases at Charleston, S C.

The following table gives the rates per 100,000 population for 103 cities for the five-week period ended June 19, 1926, compared with those for a like period ended June 20, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 103 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926 The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below

Summary of weekly reports from cities, May 16 to June 19, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

Kwantung Dairen	0	0	0	0	6	2

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

British India.—Chittagong, Cochin, Tuticorin.

Federated Malay States—Port Swettenham

Straits Settlements—Penang, Singapore.

Dutch East Indies.—Batavia, Surabaya, Samarang, Cheribon, Belawan Deli, Palembang, Sabang, Makassar, Menado, Banjermasin, Balik-Papan, Tarakan, Pontianak, Padang.

Sarawak—Kuching.

British North Borneo—Sandakan.

Portuguese Timor—Dilly

Philippine Islands—Manila, Iloilo, Jolo, Cebu, Zamboanga.

French Indo-China—Turane

Formosa—Keelung.

Japan—Nagasaki, Yokohama, Osaka, Moji, Kobe, Niigata, Tsuruga, Hakodate.

Korea.—Chemulpo, Fusan.
Kwantung.—Port Arthur.
Manchuria.—Antung, Mukden, Changchun, Harbin.
U. S. S. R.—Vladivostok.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.
New Guinea.—Port Moresby.
New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia.—Noumea.
Hawaii.—Honolulu.

AFRICA

Egypt.—Alexandria, Port Said, Suez.
Anglo-Egyptian Sudan.—Port Sudan.
Eritrea.—Massaua.
French Somaliland.—Jibuti.
British Somaliland.—Berbera.
Italian Somaliland.—Magadiscio.
Kenya.—Mombasa.
Tanganyika.—Dar-es-Salaam.
Seychelles.—Victoria.
Mauritius.—Port Louis.
Madagascar.—Tamatave, Majunga.
Zanzibar.—Zanzibar.
Portuguese East Africa.—Mozambique, Beira, Lorenço Marques.
Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from:

British India.—Rangoon, Calcutta.

CHINA

Smallpox—Typhus fever—Chungking district.—Under date of May 1, 1926, smallpox and typhus fever were reported among the military at Wanhsein, in the consular district of Chungking, China. A death from typhus fever was reported at Ichang, in a member of the foreign population.

GREAT BRITAIN (SCOTLAND)

Prevalence of certain infectious diseases—Glasgow—April 25–May 29, 1926.—During the five-week period ended May 29, 1926, 515 cases of measles with 34 deaths were reported at Glasgow,[1] Scotland; diphtheria including membranous croup and scarlet fever were reported prevalent with 215 cases and 373 cases, respectively; lethargic encephalitis acute, with 11 cases, tuberculosis (pulmonary), 220 cases; other forms of tuberculosis, 146 cases. Population, estimated, 1,034,500.

[1] Public Health Reports, Jan. 22, 1926, p. 154, Apr. 2, 1926, p. 639, May 7, 1926, p. 910, June 18, 1926, p. 1258.

GREECE

Plague—Patras—May 27, 1926.—Two cases of plague, one of which terminated fatally, were reported at Patras, Greece, May 27, 1926. The cases occurred in the same family and in a quarter of the city not far from the customhouse and the port.

INDIA

Plague-infected rats—Rangoon—January–April, 1926.—During the four-month period, January to April, 1926, inclusive, 57 plague-infected rats were reported found at Rangoon, India. During the same period, 140 cases of plague with 129 deaths were reported at Rangoon, of which 12 cases were stated to have been imported.

LATVIA

Communicable diseases—April, 1926.—During the month of April, 1926, communicable diseases were reported in the Republic of Latvia as follows:

April, 1926

Disease	Cases	Disease	Cases
Diphtheria	68	Rabies	2
Dysentery	4	Scarlet fever	306
Lethargic encephalitis	1	Smallpox	3
Malaria	1	Tetanus	2
Measles	184	Tuberculosis	61
Mumps	40	Typhoid fever	47
Paratyphoid fever	4	Whooping cough	56
Puerperal fever	7		

Population estimated, 1,850,000

MADAGASCAR

Plague—April 1-15, 1926.—During the period April 1 to 15, 1926, 42 cases of plague with 30 deaths were reported in the Island of Madagascar. The types of the disease were: Bubonic with 14 cases, pneumonic, 18 cases, septicemic, 10 cases. For distribution of occurrence, according to locality, see page 1458.

MALTA

Communicable diseases—May 1-31, 1926.—During May, 1926, communicable diseases were reported in the Island of Malta as follows: Bronchopneumonia, 7 cases; chicken pox, 45; diphtheria, 7; erysipelas, 6; influenza, 4; lethargic encephalitis, 3; Malta (undulant) fever, 41; measles, 96; pneumonia, 20; scarlet fever, 1; trachoma, 80; tuberculosis, 20, typhoid fever, 20; whooping cough, 12. Population, civil, estimated, 223,088.

MEXICO

Gastroenteritis—Chihuahua.—During the period May 25 to June 13, 1926, gastroenteritis was reported present at Chihuahua, Mexico The water supply of the city was stated to be unfiltered

Smallpox—San Antonio de Arenales—During the period January to June, 1926, smallpox was reported present, with a number of cases, in a community settlement at San Antonio de Arenales, situated about 100 miles distant from Chihuahua

TUNISIA

Plague—Kairouan and vicinity.—Under date of June 9, 1926, 12 cases of plague with 8 deaths were reported in Tunisia. Of these, three cases occurred in the city of Kairouan and nine cases in a territory 30 miles south of Kairouan. It was stated that a sanitary cordon had been established and that an intensive campaign of antiplague inoculation was being carried out

UNION OF SOUTH AFRICA

Plague—Cape Province—Orange Free State—May 9-15, 1926.—During the week ended May 15, 1926, plague was reported in the Union of South Africa as follows *Cape Province*—Three European cases, of which two ended fatally, occurring at a farm in the Middelburg District, *Orange Free State*—one fatal case, native, at Protestpan, 15 miles distant from Bultfontein.

Typhus fever—April, 1926—During the month of April, 1926, 85 cases of typhus fever, with 14 deaths, occurring in the colored population, and 2 cases in the European population, were reported in the Union of South Africa. For distribution of occurrence, according to province, see page 1459.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

The reports contained in the following tables must not be considered as complete or final as regards either the lists of countries included or the figures for the particular countries for which reports are given

Reports Received During Week Ended July 9, 1926 [1]

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain. (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual request.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

PUBLIC HEALTH REPORTS

VOL. 41 JULY 16, 1926 NO. 29

THE SO-CALLED ACTION OF ACID SODIUM PHOSPHATE IN DELAYING THE ONSET OF FATIGUE

By FREDERICK B FLINN, Associate Physiologist, Office of Industrial Hygiene and Sanitation, United States Public Health Service

Introduction

Emden's report (1) regarding the effects of acid sodium phosphate administered to German soldiers during the late war, to miners, and to animals, for the purpose of delaying the onset of fatigue, aroused considerable interest in the public mind. The study presented in this paper was prompted by the desire to determine, if possible, whether or not the results reported by Emden were generally applicable or were due to conditions peculiar to Germany and other European countries on account of the late war

The position that phosphate occupies in the metabolism of the muscle has been investigated by various workers in the past. The production of an excess of acid sodium phosphate during exercise was suggested by Lee and others as being one of the factors in causing fatigue in the isolated muscle as indicated by a lowered muscular efficiency. MacLeod (1899) (2), studying the distribution of the inorganic and organic phosphate in the muscle of dogs exercised in a treadmill, found that there was a decrease in the water soluble organic phosphate with a corresponding increase in the inorganic phosphate. At a later date (1914) he was inclined to explain these results as being due to the action of the lactic acid, formed during exercise, on the organic compound.

Meigs (3), in discussing the function of inorganic phosphate in the physiology of striated muscle, suggests that the relaxation of the contracted muscle is brought about by the combining of the lactic acid with the potassium phosphate contained in the muscle fiber. That there is a relationship between the lactic acid and phosphoric acid in the muscle is apparently confirmed by the work of Emden and his school. They report that if the skeletal muscle of the dog is kept standing in bicarbonate at 40° C., phosphoric as well as lactic acid will be liberated, and, further, that under certain easily maintained experimental conditions the newly formed phosphoric acid is almost equimolecular with the newly formed lactic acid. On the basis of this evidence they were led to the conclusion that there is present in the muscle a special lactic acid forming substance, different from the usual carbohydrate, to which they have given the name "lactacidogen."

The reactions of this substance resemble very closely the reactions of hexophosphoric acid formed during alcoholic yeast fermentation. If any one of the carbohydrates is added to pressed muscle juice there is no increase in the production of lactic acid, while if the sodium salt of this hexose-phosphoric acid from yeast is added to the pressed muscle juice, it decomposes into lactic and phosphoric acids.

Encouraged by his research on "lactacidogen," Emden attempted, during the late war, to increase the muscular efficiency of the German soldier by the oral administration of acid sodium phosphate in sublaxative doses. The results he reported were impressive, and again in his laboratory he showed a sharp rise in the amount of work done on the bicycle ergometer by the soldier after an administration of this salt The effect of the phosphate lasted, in most of his experiments, for 48 hours, and frequently showed a further rise in the amount of work done in the second 24 hours over the first 24 hours. It was his custom to give the phosphate in a 4 per cent cane-sugar solution, which introduces another factor in view of the claim that cane sugar, under certain conditions, will give an increased muscular efficiency.

His reasoning as to the oral administration of acid sodium phosphate for the purpose of delaying the onset of fatigue or for producing greater muscular efficiency is not quite clear to us, especially when we take into consideration all the known facts about the metabolism of phosphates. It appears to be the consensus of opinion that ordinary activity or vigorous exercise by a trained man does not increase the excretion of phosphorus. It is only when the exercise is so strenuous as to cause tissue destruction that an excess outgo of phosphorus and other tissue katabolites occurs. The greatest excretion of phosphorus occurs in this case after the termination of the exercise and may persist for several days. Lehmen (4) found that the inorganic phosphate in rabbit's blood remained constant within biological limits, while if through any means it should be increased to four or five times the normal concentration it would return to normal inside of four hours. We ourselves have examined the blood of dogs within an hour and a half after the oral administration of sublaxative amounts of acid sodium phosphate and could not detect any increase in the phosphate content of the blood. Underhill (5), working with solutions of mono-, di-, and tri-sodium phosphate, which he injected subcutaneously, found considerable increase in the urinary phosphate, 70 to 100 per cent of the injected phosphate being recovered in the urine. He also noted that the character of the diet and nature of the phosphate had no apparent influence on the percentage of the injected phosphate excreted in the urine. Again, Meigs and coworkers (6) call attention to the fact that the urinary excretion of phosphorus is actively influenced by the concentration of the inorganic

phosphate in the blood plasma. Their results indicated that it is influenced by another factor, which was connected with the acid equilibrium of the body. Kingo Goto (7) seems to have confirmed this last observation by showing that the muscle lost markedly in phosphorus and potassium and somewhat in sodium during acidosis.

It may be that Emden's subjects, on account of the nutritional conditions, underwent greater tissue destruction than would occur in a well-nourished man, and that the phosphorus requirements of the body were satisfied by the intake of the acid sodium phosphate. Bauer (8) writes: "As a rule we take in with our food a far larger quantity of salts than is necessary for the replacement of those of the tissues. The excess is excreted with the urine, and only when an increase in the body weight occurs is any large amount of salts retained in the body." According to Sherman (9), in 41 per cent of 150 dietaries of American families or larger groups examined, and which were believed to be fairly representative, the phosphorus content was found to be below the standard.

Present Study

Outline of present study.—It was decided to divide the study into three parts, as follows:

(1) Animal experiments.

(2) Subjective experiments in which the more general physiological effects of acid sodium phosphate were studied

(3) A study of the increase in production in man. During this part of the study we purposely refrained from asking any questions of those participating in the test, so as to avoid introducing any psychological factor into the experiment.

Preparation and administration of the acid sodium phosphate.—The phosphate was dissolved in a 4 per cent cane-sugar solution in sufficient quantity to make a 15 per cent solution of the salt, so as to duplicate Emden's dosage. Each subject was tested as to his or her tolerance toward the salt, as it was our aim to keep the dosage down to sublaxative amounts. Our experience indicates that in human beings this dosage varies from 2½ to 7 grams. Once the dosage was determined for the individual, it was not found necessary to change the amount during the study. Any increase was sure to produce a laxative effect. As a rule, the salt was taken each morning before beginning work. Those participating in the production part of the study took the salt about breakfast time.

1. ANIMAL EXPERIMENTS

Our animal experiments proved disappointing, inasmuch as we were unable to arrive at any satisfactory base line from which to start in judging the effect on work production of an administration of acid sodium phosphate.

We used the Dourdouro strain of the albino rat in these experiments. Male rats varying in weight from 200 to 300 grams were selected and tested as to their willingness to run in the mill. These rats were placed on a balanced diet for two weeks before they were subjected to a training period. This training period consisted in running the rats for a short period each day until they had lost their flabbiness and their muscle became firm. The weights of the rats remained constant or increased slightly during the period that they were being conditioned for the actual fatigue tests.

Apparatus.—We made use of the revolving drum for fatiguing the rats. The apparatus consisted of six drums, 16 inches in diameter and 10 inches wide, driven at a uniform speed by an electric motor, which permitted us to exercise six rats at the same time. These drums were built of one-quarter-inch-mesh galvanized wire net and were lined over three-fourths of the width with corrugated rubber matting. This was necessary because it was found that when the rats ran for a long period on the naked wire their feet became sore. It also had an advantage, as it prevented their hanging on to the wire netting and being carried around with the cage, and which, as a rule, resulted in torn toenails.

The rate at which the drums should revolve received considerable attention, and it was finally decided after much experimental observation to turn them at a speed of eight revolutions per minute. This kept the rats moving at what appeared to be a natural running gait; whereas if the speed were increased very much they became bewildered, clung to the sides of the wheel, and were thrown around and fatigued more from the rough treatment than from physical exercise.

The question which concerned us most in the animal work was the standard by which we could measure the fatigue of the rat or even determine whether the rat was really fatigued or not. It was finally decided that the rat should be kept running until it lay down on its back and did not respond to any external knocks on the side of the drum. Then, if on removal from the drum it was content to remain quiet and showed no interest in food placed near it, we considered it fatigued.

When the rats were first placed in the drum after the hardening period, it was found that they were unable to run for a longer time than six hours as determined by our adopted standard. With each successive period of running there was an increment in the running time of from three to six hours. As soon as they were able to run steadily for 24 hours, we decided to stop the drum every six hours to permit the rat to rest, eat, and drink a little. This rest period never amounted to more than half an hour each time. This procedure was considered necessary as otherwise the element of exhaustion from thirst and starvation would have complicated the results. In spite

of all precautions we were unable to arrive at a base line. Rats that would run for 50 hours would jump to 90 hours in the next running period. On the other hand, rats that had run 50 hours would drop down to 10 and 12 hours. Autopsies on some of the rats suggested that the variations in length of runs were due to pathological heart conditions.

After working with the rats for three months we decided to abandon this part of the study because of the inadvisability of proceeding with experiments in which no normals or base lines could be obtained. Our previous work with dogs did not encourage us to use them in the place of rats.

2. SUBJECTIVE EXPERIMENTS

For the purpose of studying the general physiological effects of the salt on human beings, we were fortunate in having 40 persons volunteer to take the salt under our direction for a period of two months. This group consisted of medical men, scientific workers, stenographers, and laboratory attendants. From time to time we substituted acid sodium tartrate solution without telling the individual that it was being done As a check on their subjctive observations we kept a record of body weight and blood pressure. The value of these data was proved in various instances and was interesting from a psychological viewpoint. On the whole, our reports thoroughly confirmed the worthlessness of most subjective studies in this field, but in this mass of contradictory evidence certain points stand out clearly, and only these need be considered here.

The consensus of opinion is that the group, as a whole, felt better for the taking of the phosphate and none felt any ill effect. All agreed that the reason for the general improvement was a more regular evacuation of the bowel. This is not surprising when one considers the great majority of persons in our own country who are suffering from various degrees of constipation. Acid sodium phosphate is recognized by the medical profession as having a laxative effect. The profession has also used this salt in the treatment of pyelitis, either to render the urine acid or to increase its acidity for the purpose of assisting the action of hexamethylentetramine, which is active only in acid solution. Acid sodium phosphate is more pleasant to take then other saline laxitive; it is positive in its effects, without the griping and uncomfortable symptoms so often complained of when other purgatives are taken.

As has been previously stated, one of the premises of our work was the avoidance of laxative doses, and great care was taken to avoid any flushing effect. Still, the fact remains that it did stimulate the alimentary tract to some extent, and that the evacuations of those taking the salts were more regular and of a free nature, requiring no straining at the stool. Moreover, the number of evacuations in-

creased to two or three a day. One feature to be noticed was the absence of any binding effect on the days on which the salt was not taken, and that the beneficial stimulation of the intestinal tract appeared to last for several days. Over 80 per cent of those volunteering for the study were suffering from various degrees of constipation, and felt the beneficial effect brought about by the elimination of body waste. It was noticeable that those subjects who did not report any improvement were those who were feeling fit and well and were regular in their habits and hence did not need laxative effects of the acid sodium phosphate.

The benefits accruing from taking the salts manifested themselves by increased appetites, increased weight, absence of bad breath, disappearance of headaches, and a slight drop in blood pressure. Persons who were accustomed to going without breakfast found that they were now compelled to eat a substantial meal. Several reported that they were able to remain up later at night and awoke the next morning feeling less tired than had been their habit at the beginning of the experiment. Unfortunately the type of work in which this group were engaged prevented any study of improvement in their productive ability.

Dujardin-Beaumetz, in discussing the utility of adding phosphate to food and the favorable results which have been noticed, suggests that they probably are due to a regulatory action on the alimentary tube, or to some acid element which it conveys to the stomach, or to some other indirect result.

3. INCREASE IN PRODUCTION DUE TO INGESTION OF ACID SODIUM PHOSPHATE

Through the cooperation of the Federal Post Office Department, in Washington, we were able to obtain the assistance of 30 girls employed in the auditing section for this part of the study. The girls volunteered to take the salt regularly for us on the condition that if they felt any ill effect they could drop out of the test at any time.

These girls were working card-perforating machines, which are operated electrically and controlled by 12 keys arranged in four rows. Most of the girls use the touch system, involving at least three fingers on the right hand, while the left hand is used in feeding the cards into the machine. The girls complain that their arms become tired from the operation. They work in well lighted and ventilated rooms. The hours of employment are from 9 a. m. until 4.30 p. m., with half an hour for lunch from 12 until 12.30, and with 15 minutes' rest periods in the morning and afternoon, making actual operation of the machine six and a half hours. These girls are practically engaged in piecework, as their pay for any six months

is determined by the average daily number of cards correctly punched during the previous six months.

The office keeps a record of the work of each girl from the first day she begins to work until she leaves the employment of the department, and because of this record they presented an ideal group on which to make such a study as we were conducting.

As a control group we used the record of girls employed at the same time who were not taking the phosphate and did not know that they were being used for that purpose.

Records of production and errors in the city post office were obtained for the period from February 15, 1924, to May 31, 1924, the phosphate being given from March 13 to April 24 to 30 girls.[1] A group of 20 girls, for whom records were obtained for the entire

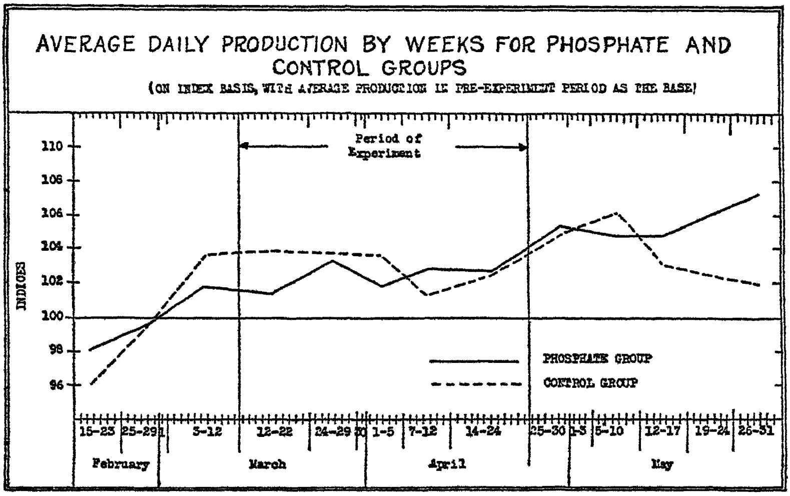

FIG 1

period, served as controls. The control group was selected at random from the other girls performing the same operation.

The records give the production for each day for each girl. Whenever the girl's time at the office was less than seven hours, the exact time was put down, but all those who showed less than six and three-fourths hours at the office were excluded from our records for that day.

First is presented a table and graph giving the average daily production by weeks throughout the period for two groups—those given the phosphate, and those serving as controls (Tables 1 and 2; Figs. 1 and 2.) For the purposes of the graph, the averages have been reduced to indices, using as the base the average daily production in the preexperiment period. Since the phosphate admin-

[1] Records for two (Nos 26 and 126) of the 30 girls were incomplete, hence the study has been limited to 28 girls.

istration was commenced and ended in the middle of the week, the data have been divided at these points, and the incomplete parts combined with the preceding or succeeding week, as the case may be.[2]

TABLE 1 —*Average daily production by weeks for phosphate and control group*

Period	Average daily production		Indices [1]	
	Group receiving phosphate	Control group	Group receiving phosphate	Control group
Feb 15–23 [2]	3,125	2,744	98.1	96.0
Feb 25–Mar. 1	3,170	2,835	99.5	99.2
Mar 3–12	3,241	2,961	101.8	103.6
Mar 13–22	3,228	2,961	101.4	103.6
Mar 24–29	3,291	2,964	103.4	103.7
Mar 31–Apr 5	3,242	2,959	101.8	103.6
Apr. 7–12	3,276	2,890	102.9	101.2
Apr 14–24	3,274	2,928	102.8	102.5
Apr. 25–May 3	3,360	2,997	105.5	104.9
May 5–10	3,340	3,033	104.9	106.2
May 12–17	3,345	2,948	105.0	103.2
May 19–24	3,381	2,928	106.2	102.5
May 26–31	3,419	2,916	107.3	102.1
Average, Feb 19–Mar 12	3,185	2,857	----------	----------

[1] Base is the average daily production for period from Feb 15 to Mar 12
[2] Feb 15 and 16 and days of other incomplete weeks are combined with preceding or succeeding periods.

The graph indicates a general upward trend for the phosphate group throughout the three and one-half months. The rise does not appear to be connected with the phosphate treatment, as it commenced in the preexperiment period and continued through May. Records for June were not obtained, but it would be possible to have them if it were felt worth while to put this additional time on the work. The fact that the phosphate group has a higher average production than the other group is of course of no significance. We are concerned only with the changes in the production curve.

The control group, being smaller, fluctuates more than the other group, but also suggests an upward trend. The control curve crosses the phosphate curve in each period. Certainly no evidence of any effect due to the phosphates is offered by this table and graph.

That the upward trend noted above occurs chiefly among the workers with least efficiency is indicated by Table 2 and Figure 2, which are similar to the first table and graph, but are limited to the 10 most efficient workers in each group (those with the 10 highest averages in the preexperiment period.)[3]

[2] February 15 and 16 were also combined with the succeeding week to avoid too great fluctuation.
[3] The numbers of the girls used for this table and graph were. *Phosphate group* 10, 24, 27, 43, 50, 81, 85, 100, 106, 114. *Control:* 9, 11, 14, 45, 63, 67, 68, 89, 92, 121. See Tables 4 and 5 for individual production in preexperiment period.

TABLE 2 —*Average daily production by weeks for 10 most efficient workers in each group* [1]

Period	Average daily production		Indices [2]	
	Group receiving phosphate	Control group	Group receiving phosphate	Control group
Feb 15-23 [3]	3,615	3,518	97 7	99 6
Feb 25-Mar 1	3,687	3,541	99 6	100 3
Mar 3-12	3,778	3,533	102 1	100 1
Mar 13-22	3,711	3,556	100 3	100 7
Mar 24-29	3,731	3,545	100 8	100 4
Mar 31-Apr 5	3,723	3,532	100 6	101 4
Apr 7-12	3,736	3,607	100 9	102.2

Apr 25-May 3	3,761	3,541	101 6	100 3
May 5-10	3,743	3,545	101.1	100.4
May 12-17	3,708	3,520	100.2	99 7
May 19-24	3,711	3,526	100 3	99 9
May 26-31	3,730	3,531	100 8	100 0
Average, Feb 15-Mar 12	3,701	3,531		

[1] Ten with highest average daily production during preexperiment period
[2] Base is the average daily production for period from Feb 15 to Mar 12
[3] Feb 15 and 16 and days of other incomplete weeks are cobmined with preceding or succeeding periods.

Here little or no upward trend is observable. There is again no indication that the group given phosphates showed any increase in production as a result of this treatment, either when compared with the periods before and after the experiment, or when compared with

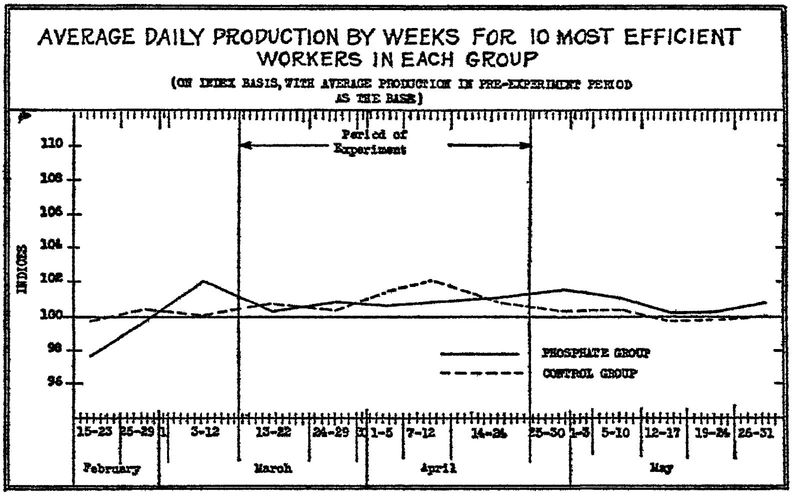

FIG 2

the control group. The phosphate group reached one of its highest points before the experiment was begun, and the other after it was ended.

To be entirely certain of our conclusions, however, it seemed well to study also the individual workers, as it was possible that a few

might have shown increased production without affecting the total group appreciably The next two tables (3 and 4) therefore give for the three periods (before the experiment, during the experiment, and after the experiment) the average daily production of each worker, both those given phosphates and those not given phosphates. For convenience, these averages are reduced to indices, using as the base the production during the preexperiment period. A 10 per cent increase, obviously, in production during the second period over the first period, therefore, would be indicated by the figure 110 in the second period. It is observed that in no instances among those given phosphates does the index figure for the second period reach 110, and that in those cases where it is somewhat high it is likely to be still higher in the third period (thus suggesting that the increase probably is connected with some other factor independent of the effect of the phosphate). The tables for the phosphate group and for the control group are very similar and the differences appear to be due to chance.

FIG 4

To save space in the table the averages have been given without the final place. Thus the figures are one-tenth of the actual averages. Parts of weeks have been combined with preceding and succeeding weeks, as in Tables 1 and 2. No pronounced rise during the experiment period is anywhere observable.

The records also gave the number of errors made by the girls. Table 6 summarizes the results. During the experiment period the average number of errors per day was not significantly different from that occuring before the experiment or after it. The control group shows the same chance distribution. It is, of course, of no importance that the phosphate group made slightly more errors than the control group throughout.

TABLE 6.—*Average daily number of errors made in the three periods by the phosphate and control groups*

Period	Group receiving phosphates	Group not receiving phosphates
Feb 15–Mar 12	1 94	1 69
Mar 13–Apr 24	1 99	1.73
Apr. 25–May 30	1 93	1 64

SUMMARY

1. The impossibility of determining a base line from which to judge fatigue in an animal seems fairly well established.
2. The benefits derived from ingesting acid sodium phosphate appear to depend on its stimulating action on the intestinal tract.
3. The ingestion of acid sodium phosphate does not appear to increase muscular efficiency.
4. The feeling of well-being experienced by the group which was studied to determine the general physiological effects of the salt was probably, in part, due to increased elimination of body wastes.

PUBLIC HEALTH ENGINEERING ABSTRACTS

A Study of Milk Problems in Canada. Committee of the Canadian Public Health Association, Dr. M M. Seymour, chairman. *Public Health Journal*, vol. 17, No. 5, May, 1926, pp. 241–244. (Abstract by R. E. Tarbett.)

The authors discuss the findings of the committee appointed for the purpose of making a study of "Milk Problems" and reporting its findings at the annual meeting of the Public Health Association of Canada.

The report is based on a questionnaire addressed to the various health departments (city and provincial) of Canada. Statistics have been compiled from the data furnished in the replies, and have been added as an appendix to the report. The report is in the nature of a preliminary study and outline of the difficulties confronting the public health officer in safeguarding the milk offered for sale in his community.

The authors urge the necessity of encouraging dairy farming, by every possible means, to increase the volume of supply and the number of producers. This increase in supply and number of producers will bear upon the health aspect of the question, the authors point out, as keener competition will enable the public health officer to raise the standard of production.

An average per capita consumption of 0 71 pint per day for the 21 cities reporting is compared with the per capita consumption of 0.54 pint per day in New York in 1923.

Data regarding epidemics of milk-borne disease in Canada were collected, and the results have been set down in the appendix to the report. It was noted that only two diseases, typhoid fever and scarlet fever, are named as occurring in the epidemics traced to milk infection, and that no records are available regarding diphtheria and septic sore throat conveyed by milk supplies. The epidemics reported on are regarded as representing only a small proportion of the outbreaks that have occurred.

The importance of safeguarding the milk supply is pointed out, as, the authors state, milk has been the means of causing more disease than any other single food.

Local problems in connection with milk control, as reported on by the various provincial and city departments of health, are set forth in the article, among which were included the following: Difficulty of insuring cleanliness in the handling of milk and in the care of cows and stables, ignorance of farmers and difficulty of reaching them in the rural districts, difficulty of enforcing pasteurization of milk.

Hog Feeding at Flint, Mich. Nahum W. Long. *Public Works*, vol. 57, No. 3, April, 1926, pp. 81–82. (Abstract by J. K. Hoskins.)

Flint, with a population of about 135,000, acquired a run-down farm about 12 miles distant that had railroad shipping facilities available and used this farm for disposal of town garbage by feeding hogs. From 1,000 to 1,700 head are maintained, depending on the flow of garbage.

Methods of feeding, soil renovating, and cleaning are described. Selection of the proper stock for feeding is emphasized and the procedure followed in keeping the animals in proper condition is outlined. The profit last year from feeding amounted to over $40,000

The Influence of Soft and of Hard Waters on the Decomposition of Sewage. J. E Purvis, chairman, Cambridge Sewage Disposal Committee. *Surveyor*, vol. 69, No. 1781, March 5, 1926, pp. 277–278. (Abstract by Rudolph E. Thompson)

It has been previously shown by the author and his colleagues that the decomposition of sewage occurs very slowly when the sewage is mixed with sea water or other saline solutions. In the present investigation experiments were carried out to determine whether the hardness of the water employed for carrying the sewage had an influence on the rate of decomposition. Mixtures of domestic sewage and soft water (distilled) and of domestic sewage and hard water (18 5° and 25°) were aerated under parallel conditions at varying rates and for different periods of time The results of these experiments showed that oxidation occurred much more rapidly in the soft-water mixtures than in the hard-water mixtures, the free and albuminoid ammonia and oxygen consumed values in every instance being lower in the former than in the latter after aeration. The nitrites were irregular, but the nitrates were invariably higher with the soft water. It was also observed that the hard-water mixtures were more opalescent in appearance, probably due to the precipitation of colloidal substances. This would increase the amount of sludge deposited during tank treatment, thus reducing the load on the subsequent treatment processes employed The importance of considering these factors in comparing the results of different plants and methods of purification is emphasized.

Recent Experiments in Dewatering Sewage Sludge. Herbert D Bell, manager and chemist, Barnsley Sewage Works. *Surveyor*, vol. 69, No. 1775, January 22, 1926, pp. 79–81. (Abstract by Rudolph E. Thompson.)

Experiments are described in which sewage was dried from moisture content of 98 per cent to about 80 per cent by draining for about 20 hours on a sludge bed consisting of land drains, overlaid with granite and topped with sand. The sludges experimented with were of three types—liquid sludge produced by precipitation with lime (4 g. p. g.), plain sedimentation sludge, and limed sedimentation sludge. The presence of lime, added either prior or subsequent to

settling, facilitated dewatering, the plain sedimentation sludge requiring 68 hours to drain to 80 per cent moisture, whereas that containing lime required only 20 hours The effluent was perfectly bright and clear Beds prepared with various sands and with ashes as top dressing (3 inches) were compared and it was found that sand with smooth, rounded grains gave the best results, and that removal of sludge cake could be carried out more readily than in the case of ashes and sand with rough angular grains The drying process appears to continue when the cake is removed and tipped on to small heaps, the sludge heating up and emitting large volumes of water vapor when disturbed.

Sewage Sludge. Anon. *American Journal of Public Health*, vol. 16, No 1, January, 1926, pp 39–42. (Abstract by A L Dopmeyer)

This article is the progress report of the Committee on Sludge of the A P H A., presented at the meeting in October, 1925.

Increased interest in the use of sewage sludge on the part of the agriculturist and fruit grower, and the demand upon the part of the golf clubs, flower growers, and fertilizer manufacturers for the organic nitrogen in the sludge when reduced to a dry basis are given as the outstanding features of the progress made during the year in sludge disposal.

Particular instances are cited of attempts at economically disposing of sewage sludge from some of the larger sewage plants, particularly those of the activated sludge type. It is suggested that the activated sludge process might be used more if some method were discovered for economically disposing of the sludge from both large and small plants and the committee recommends that caution be used in approving plans for new projects

The Relation of Storage Water Supply Lakes to Malaria. J. A. Le Prince, United States Public Health Service. *Journal North Carolina Section American Water Works Association*, vol. 3, No. 1, pp. 42–50. (Abstract by L. D. Fricks.)

The dangers of increasing mosquito production, and, perhaps, malaria prevalence, by impounding waters are clearly pointed out in this paper. The problem of impounding city water supplies without increasing these dangers has become serious for southern cities and will continue so until the engineer responsible for planning and constructing these reservoirs familiarizes himself with and applies proper measures for the control of mosquito production. An outline is given of regulations for impounded waters as suggested by the United States Public Health Service and adopted by several Southern States.

The cardinal points of these regulations are as follows: Care of laborers employed in construction work; clearing of reservoir basin;

prevention of log jams; drift and flotage; fluctuation of water level; clearing of shore line; regular inspections for mosquito production; stocking with *Gambusia*, control of separate pools and seepage places around reservoirs; and licensing by State board of health.

ILLINOIS ADOPTS REGULATIONS REGARDING ZINC STEARATE CONTAINERS

The Illinois Department of Public Health recently adopted regulations relating to containers for zinc or other stearate toilet or dusting powders The said regulations went into effect June 10, 1926, and read as follows:

Whereas it has been reported to the Department of Public Health of the State of Illinois that accidents and deaths have been caused from the inhaling of stearate of zinc dusting powders by children, and

Whereas, by investigation and survey, the said department of public health has secured data showing numerous accidents and deaths which were caused from the inhaling of such powders by children; and

Whereas, by investigation, research, and survey, the said department of public health has determined that stearate of zinc dusting powders are poisonous when inhaled; and

Whereas it has been determined by the said department of public health that the lack of proper containers for such stearate of zinc dusting powders is the underlying cause of these accidents and deaths; and

Whereas it is determined by the said department of public health that such accidents and deaths from the inhaling of stearate of zinc dusting powders will be prevented if such stearate of zinc dusting powders are dispensed in containers so constructed as to prevent seepage or spilling from the joints and seams and equipped with an automatic closing top;

Therefore the Department of Public Health of the State of Illinois, pursuant to statutory power vested in this department, hereby adopts and promulgates the following rules and regulations

RULE I. No person, persons, company, or corporation shall, from and after the 10th day of June, A D 1926, sell, offer for sale, or dispense to the general public, zinc or other stearate toilet or dusting powders, or toilet or dusting powders containing stearate of zinc or other stearate having similar physical properties as one of the ingredients in excess of 10 per cent by weight, unless such dusting powders shall be sold, offered for sale, or dispensed in containers which comply with the specifications set forth by these rules.

RULE II. Containers shall be substantially constructed. All joints and seams shall be closed by crimping, soldering, or equivalent method so as to effectively prevent separation or leakage at seams or joints.

RULE III Containers shall be equipped with an extreme top with a substantial self-closing device which will remain closed at all times when not in use. The self-closing device shall be of sufficient strength to retain a closing tension of not less than 2 pounds, or 907 2 grams, throughout the ordinary life of the container in order to prevent its operation by an infant.

RULE IV. The extreme top shall have a diameter of not less than 2 inches, or 50 8 millimeters, in order to prevent its insertion into the mouth of an infant. The opening or openings in the top shall not exceed in total area 40 square millimeters, and the diameter of no opening shall exceed 3 millimeters.

RULE V Containers shall bear in plain sight and separated from other reading matter the following label

CAUTION—THIS POWDER MAY BE INJURIOUS IF INHALED

Penalty—Any person, persons, company, or corporation who violates or refuses to comply with and obey these rules and regulations shall be subject to prosecution for the violation or refusal, and shall be subject to fine of not to exceed $200 for each offense or imprisonment in the county jail not to exceed six months or both.

It shall be the duty of all local boards of health, health authorities and officers, police officers, sheriffs, constables, and all other officers and employees of the State or any county, village, city, or township thereof, to enforce the rules and regulations hereby adopted and set forth

COURT DECISIONS RELATING TO PUBLIC HEALTH

Authority of legislature to abolish or reduce term of office of parish board of health.—(Louisiana Supreme Court, Gouaux *v.* Smith et al., 107 So 466, decided January 4, 1926) In June, 1920, a board of health of three members was appointed for the parish of Lafourche and the plaintiff in this case was made chairman of the board and ex officio parish health officer. The term of office of the members was four years.

A 1920 statute called a constitutional convention and a proviso in the act forbade the convention to enact or adopt any article or provision reducing or shortening the terms of office of the public officials throughout the State, whether elected or appointed, and whether State, district, parish, or municipal officers The new constitution adopted in 1921 contained the following in article 22:

Sixth All officers, executive, legislative and judicial, State, parish, or municipal, who may be in office at the adoption of this constitution, or who may be elected or appointed before the election or appointment of their successors as herein provided, shall hold their respective offices until their terms shall have expired, and until their successors are duly qualified, as provided in this constitution, unless sooner removed, as may be provided by law, and shall receive the compensation now fixed by the constitution and laws in force at the adoption of this constitution, except as herein otherwise provided

The constitution of 1898 contained the following provision:

The general assembly shall create for the State and for each parish and municipality therein, boards of health, and shall define their duties, and prescribe the powers thereof.

A similar provision was incorporated in the 1913 and 1921 constitutions.

Act 79 of the laws of 1921, which was an act to carry into effect the foregoing 1921 constitutional provision regarding boards of health, in terms did away with the boards of health theretofore created and

created new boards as their successors. Pursuant to act 79 a new board of health for the parish of Lafourche was appointed in March, 1922, composed of five members for a term of four years. The plaintiff was one of the members appointed but another member was made parish health officer. The plaintiff did not qualify under the new appointment but brought suit contesting the claims of the other new appointees and particularly the claim of the newly appointed health officer. Plaintiff's contention was that act 79 of 1921, so far as it attempted to shorten the term of office of the members of the parish board of health appointed in June, 1920, and particularly so far as it attempted to shorten plaintiff's term of office as parish health officer, was violative of the prohibition imposed by the 1920 act calling the constitutional convention and of the proviso quoted from article 22 of the 1921 constitution.

Judgment of the lower court was for the plaintiff, but the supreme court decided that the legislature was not deprived of its authority to abolish the offices of members of parish boards of health or to reduce the term of such offices. The court was of the opinion that the restriction in the act calling the constitutional convention was imposed upon the convention only and not upon the legislature, and that, as the portion of the constitution relating to parish boards of health did not fix the term of office, the legislature had authority to fix it. The court also held that the language quoted from article 22 of the constitution did not interfere with the authority which the legislature had to remove any public officer by abolishing his office, provided it was an office which the legislature had authority to create.

Orders of State board of health forbidding use of schoolhouses until insanitary and unsafe conditions had been remedied held appealable.—(Indiana Appellate Court, State Board of Health *v.* Ort, Township Trustee, 151 N. E. 31, decided March 12, 1926.) The State board of health, after hearing, entered orders condemning several schoolhouses because of certain insanitary, unsafe, and dangerous conditions, and prohibited their use for school purposes after a certain date unless and until the said conditions had been remedied. The township trustee appealed from these orders to the county circuit court. The lower court sustained the appeal and on further appeal by the State board of health the appellate court affirmed the judgment of the lower court. The question was presented to the appellate court as to the right of the township trustee to appeal from such orders of the State board of health. Chapter 90 of the laws of 1919 provided that "an appeal shall hereafter lie from all decisions of the State Board of Health of Indiana in any matter involving the building, changing, or condemnation of any school building in the State of Indiana." The

appellate court held that "The orders of the State board of health as to the schoolhouses referred to are orders which involve the changing of the building, within the meaning of the act [ch. 90] of 1919, supra, and that the appeal to the circuit court was authorized."

Power of State to prohibit the sale, possession, etc., of peyote (pellote).—(Montana Supreme Court; State *v.* Big Sheep, 243 P. 1067, decided January 26, 1926.) In this case, involving the possession of peyote by the defendant, an Indian, in violation of chapter 22 of the laws of 1923, the supreme court stated that "It was clearly within the power of the legislature to determine whether the practice of using peyote is inconsistent with the good order, peace, and safety of the State."

Conviction under State pure food law upheld.—(Wisconsin Supreme Court; Day-Bergwall Co. *v.* State, 207 N. W. 959; decided March 9, 1926.) A company manufactured and sold a compound for use in flavoring foods and confections. This compound was for use in place of vanilla extract and it was conceded that the compound was not injurious to the public health. However, caramel was used in the compound and this gave it a coloring similar to vanilla extract. It was charged that this was in violation of that portion of the State pure food law which declared an article of food to be adulterated "if it is colored or flavored in imitation of the genuine color or flavor of another substance." The conviction of the company in the lower court for violation of the above quoted portion of the law was affirmed by the supreme court, which held the law to be valid.

DEATHS DURING WEEK ENDED JULY 3, 1926

Summary of information received by telegraph from industrial insurance companies for week ended July 3, 1926, and corresponding week of 1925. (From the Weekly Health Index, July 8, 1926, issued by the Bureau of the Census, Department of Commerce)

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

Reports for Week Ended July 10, 1926

ALABAMA	Cases

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week

State	Cerebrospinal meningitis	Diphtheria	Influenza	Malaria	Measles	Pellagra	Poliomyelitus	Scarlet fever	Smallpox	Typhoid fever
May, 1926										
California	16	454	77	6	2,047	9	11	573	144	88
Hawaii	1	20	95	--------	10	--------	0	2	0	7
June, 1926										
Arizona	0	5	2	0	30	--------	0	31	0	30
Connecticut	5	53	16	0	1,612	--------	0	314	2	9
Indiana	1	56	76	--------	1,767	----	1	314	266	27

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended June 26, 1926. 37 States reported 1,087 cases of diphtheria. For the week ended June 27, 1925, the same States reported 1,024 cases of this disease. One hundred and two cities, situated in all parts of the country and having an aggregate population of more than 30,450,000, reported 763 cases of diphtheria for the week ended June 26, 1926. Last year for the corresponding week they reported 641 cases. The estimated expectancy for these cities was 753 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-four States reported 9,098 cases of measles for the week ended June 26, 1926, and 2,928 cases of this disease for the week ended June 27, 1925. One hundred and two cities reported 3,603 cases of measles for the week this year, and 1,677 cases last year.

Poliomyelitis.—The health officers of 37 States reported 22 cases of poliomyelitis for the week ended June 26, 1926. The same States reported 63 cases for the week ended June 27, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 2,127 cases: last year, 1,275 cases; 102 cities—this year, 1,240 cases; last year, 648 cases, estimated expectancy, 572 cases.

Smallpox.—For the week ended June 26, 1926, 37 States reported 355 cases of smallpox. Last year for the corresponding week they reported 444 cases. One hundred and two cities reported smallpox for the week as follows· 1926, 93 cases: 1925, 137 cases, estimated expectancy, 94 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Four hundred and forty-one cases of typhoid fever were reported for the week ended June 26, 1926, by 36 States. For the corresponding week of 1925 the same States reported 786 cases

of this disease. One hundred and two cities reported 68 cases of typhoid fever for the week this year, and 146 cases for the corresponding week last year. The estimated expectancy for these cities was 103 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 96 cities, with a population of more than 29,750,000, as follows 1926, 449 deaths, 1925, 395 deaths.

City reports for week ended June 26, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

[1] Typhus fever 1 case New York City, 1 case Baltimore, Md.
[2] Rabies in man: 1 death Los Angeles, Calif

The following table gives the rates per 100,000 population for 103 cities for the five-week period ending June 26, 1926, compared with those for a like period ended June 27, 1925. The population figures used in computing the rates are approximate estimates as of July 1,

1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 103 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, May 23 to June 26, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

British India.—Chittagong, Cochin, Tuticorin, Vizagapatam
Federated Malay States.—Port Swettenham.
Straits Settlements.—Penang, Singapore
Sarawak.—Kuching
British North Borneo.—Sandakan.
Portuguese Timor.—Dilly
Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.
French Indo-China.—Turane.
China.—Shanghai.
Formosa.—Keelung
Japan.—Nagasaki, Yokohama, Moji, Kobe, Niigata, Tsuruga, Hakodate.
Korea.—Chemulpo, Fusan.
Manchuria.—Antung, Mukden, Changchun, Harbin.
U. S. S. R.—Vladivostok

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island
New Guinea.—Port Moresby
New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia.—Noumea.
Hawaii.—Honolulu.

AFRICA

Egypt.—Alexandria, Port Said.
Anglo-Egyptian Sudan.—Port Sudan.
Eritrea.—Massaua.
French Somaliland.—Jibuti.
British Somaliland.—Berbera.
Italian Somaliland.—Magadiscio.
Kenya.—Mombasa.
Tanganyika.—Dar-es-Salaam.
Seychelles.—Victoria.
Mauritius.—Port Louis.
Portuguese East Africa.—Mozambique, Beira, Lourenço, Marques.
Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

British India.—Rangoon.
Dutch East Indies.—Batavia, Surabaya, Samarang, Cheribon, Belawan, Deli, Palembang, Sabang, Makassar, Menado, Banjermasin, Balik-Papan, Tarakan, Pontianak, Padang.
Madagascar.—Tamatave, Majunga.
Zanzibar.—Zanzibar.

CHOLERA ON VESSEL

Steamship "Kola"—In Gulf of Siam.—Under date of May 20, 1926, information was received of the occurrence of two cases of cholera, both fatal, on the steamship *Kola* en route to Koh Phra quarantine station, Siam. The cases occurred in the persons of the captain and chief engineer of the *Kola*, and developed when the vessel was entering the Gulf of Siam.

CANADA

Communicable diseases—Week ended June 19, 1926, and week ended June 26, 1926.—The Canadian Ministry of Health reports certain communicable diseases in five provinces of Canada for week ended June 19, and in seven Provinces for week ended June 26, 1926, as follows:

WEEK ENDED JUNE 19, 1926

Disease	Nova Scotia	New Brunswick [1]	Quebec	Ontario	Manitoba	Saskatchewan	Alberta [1]	Total
Influenza	1							1
Lethargic encephalitis				1				1
Poliomyelitis						1		1
Smallpox				6	1	9		16
Typhoid fever	4		9	11	3	3		30

WEEK ENDED JUNE 26, 1926

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever		2	2	1				5
Influenza	23							23
Poliomyelitis				2				2
Smallpox				6	2			8
Typhoid fever		1	2	7	1	2	1	14

[1] No report for the week ended June 19, 1926.

Measles—Edmonton (Alberta)—April–May, 1926.—During the month of April, 1926, 1,012 cases of measles with 4 deaths were reported at Edmonton, Alberta, Canada, and during the month of May, 1926, 578 cases with 1 death.

ECUADOR

Plague—Guayaquil—May 16–June 15, 1926.—Plague has been reported at Guayaquil, Ecuador, as follows May 16–31, 1926, four cases; June 1–15, 1926, one case

Plague-infected rats.—Period May 16–31, 1926—11,110 rats taken, 12 rats found plague infected; June 1–15, 1926—9 767 rats taken, 6 rats found infected.

EGYPT

Plague—May 29–June 3, 1926—Summary—During the week ended June 3, 1926, 8 cases of plague were reported in Egypt, of which 2 cases occurred in the city of Suez The total number of cases reported from January 1 to June 3, 1926, was 51, as compared with 57 during the corresponding period of 1925.

Later occurrence.—On June 8, two cases of bubonic plague with one death were reported at Suez, and on June 10 one death in hospital In the Province of Beni-Suef, June 5 to 8, three cases of bubonic plague were reported.

PERU

Plague—May, 1926—During the month of May, 1926, 23 cases of plague with 10 deaths were reported in Peru. The reported occurrence was for the departments of Ica, Libertad, and Lima. In the departments of Ancash and Cajamarca plague was reported present during the period referred to. For further information relative to locality of occurrence see page 1506.

SIAM

Further relative to cholera—Bangkok.—Epidemic cholera was reported present at Bangkok, Siam, from October 1 to December 26, 1925, with 431 cases and 258 deaths, and from December 27, 1925, to March 13, 1926, with 386 cases and 249 deaths.[1] Under date of May 14, 1926, there were reported for the period March 14 to May 8, 1926, 964 cases of cholera with 587 deaths.

Inoculation against cholera.—It was stated under date of May 15, 1926, that free inoculations against cholera were administered at the Pasteur Institute of Bangkok to all persons applying and that in the registration area of Bangkok 5,538 persons were inoculated during the week ended May 1 and 1,508 during the week ended May 8,

[1] Public Health Reports, May 21, 1926, p 1013.

1926; also that placards had been publicly posted urging the people not to drink canal water.

Hospitalization.—Hospital accommodations were stated to be insufficient and cholera patients were being treated at general hospital or at their homes. Water from the city supply was supplied by water boats to sections of the city where a shortage of water was reported.

General distribution of cholera in Siam—April 1–May 8, 1926.—During the period May 2 to 8, 1926, 698 cases of cholera with 463 deaths, were reported in Siam, and from April 1 to May 8, 2,116 cases with 1,431 deaths, occurring in 28 towns.

TUNISIA

Further relative to plague—Kairouan.[2]—Under date of June 11, 1926, the outbreak of plague reported in the vicinity of Kairouan, Tunisia, during the last weeks in May, 1926, was reported still present, with a few new cases occurring in the initial contaminated district. On June 6, a second contaminated district was discovered, with 7 cases present, at a locality south of the railway and 13 kilometers distant from Kairouan. Two plague deaths have been reported, one occurring near Sfax and one in Somra des Souassi. In both, the infection was stated to have originated at Zlass. No spread from these fatal cases was reported.

UNION OF SOUTH AFRICA

Plague—May 16–22, 1926.—During the week ended May 22, 1926, plague was reported in the Union of South Africa in the Cape Colony in Middleburg district, with the death of the case, European reported during the previous week[2] at Sakfontein, and two new cases—European, one, native, one—occurring on the same farm, the type of the disease in both cases being pneumonic. In the Orange Free State two new fatal cases occurring in natives were reported at Protestpan, in Hoopstad district, 15 miles from Bultfontein.[2]

Typhus fever.—Sporadic cases have been reported during the period referred to, one at Orange, East London district, Cape Province, one at Quibcer, Victoria East, and one at Mossel Bay.

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

PUBLIC HEALTH REPORTS

VOL. 41 JULY 23, 1926 No. 30

A STATE-WIDE SMALLPOX SURVEY IN TENNESSEE

By W. J. BREEDING, M D., Director, Division of Health Education, and E A LANE, M D, Epidemiologist, Tennessee State Department of Health

Smallpox has been more or less prevalent in Tennessee for a great many years, although it has not been present in severe form in recent years. In view of the increasing prevalance of the disease in 1923 and 1924 and the presence of a large nonimmune population in the State, combining to create a grave potential danger, the State Health Commissioner instituted a State-wide smallpox survey and educational and vaccination campaign early in 1925. The primary twofold purpose of the survey was to secure, directly from the field, specific information with regard to the smallpox situation throughout the State, and to bring the matter personally to the attention of the local civil and health authorities.

Tennessee has an area of 42,022 square miles. It is long and narrow, being 430 miles long (east and west) and 110 miles in width (north and south). It borders on eight States. On the basis of population, resources, and topography, it may be divided into three sections—east, middle, and west. In 1920, the population as of January 1 was 2,337,885, about one-fifth of whom were negroes, the percentage of negroes becoming progressively higher from east to west. The State has 95 counties, ranging in population from 2,600 (in the mountainous section of east Tennessee) to 58,000 (Hamilton County, exclusive of Chattanooga). In 1920, there were eight cities with 10,000 population or more, the largest being Memphis, with 162,351.

Chapter 519 of the Acts of 1905 provides for the notification and control of communicable diseases. Sections 8 and 9 of this act give to the local health officers and boards of health authority to adopt compulsory vaccination, without authorization by the State board of health, whenever such action is deemed necessary. Many cities and towns have ordinances requiring compulsory vaccination for school attendance, which, however, are not strictly enforced. Only a few counties—possibly not more than eight—have similar county regulations, which, for the most part, also lack enforcement.

One of the writers (Doctor Breeding) was detailed by the State commissioner of health to make the field investigation and State-wide educational campaign. Preparatory to this work, data were collected

relative to the smallpox situation in the State and throughout the country. A questionnaire was prepared to record the data, and a mimeographed letter addressed to school-teachers was prepared to accompany a brief article on smallpox and vaccination. The teachers were requested to read the article to the pupils. The subject of smallpox was also given publicity in the newspapers and in Health Briefs, the monthly bulletin of the State department of health, which had a selected mailing list of over 4,000 persons, including all physicians in the State.

A short time after the conclusion of the survey, a general letter of warning concerning the smallpox situation and an outline of an approved vaccination technique were sent to each health officer in the State.

The field work was begun May 18, 1925, and between that date and October 23 each of the 95 counties of the State was visited and inquiry was made concerning recent and past prevalence of smallpox, the approximate immunity status of the population, the cost of past control measures, and provisions made for prevention and control of future possible outbreaks of smallpox. With regard to the latter, special emphasis was placed upon the advisability of requiring all children to be vaccinated as a prerequisite for admission to school.

The accompanying table presents data relative to the occurrence of smallpox in Tennessee during the period 1916–1925.

Smallpox in Tennessee, 1916–1925

Year	Estimated population as of July 1	Deaths	Death rate [1] per 100,000	Reported cases	Case rate [1] per 100,000
1916	2,282,690	0	0	178	7.8
1917 [2]	2,298,460	4	0.17	1,108	48.2
1918	2,314,230	15	.65	3,217	139.0
1919	2,330,000	13	.56	1,874	80.4
1920	2,345,770	11	.47	3,002	128.0
1921	2,361,539	10	.42	2,913	123.4
1922	2,377,308	2	.08	567	23.8
1923	2,393,077	3	.13	1,037	43.3
1924	2,408,846	8	.33	3,145	130.6
1925	2,424,616	([3])	----------	1,810	74.7
Total	----------	[4] 66	[5] 0.31	18,851	[6] 80.1

[1] Data are not available for computing rates for white and colored separately. The 1920 Federal census gave the population of the State as 1,885,993 white (80.7 per cent), and 451,758 colored (19.3 per cent). In 1910 the per cent of total for whites and colored, respectively, was 78.3 and 21.7.

[2] Admitted to the death registration area in 1917.

[3] Data not yet available.

[4] Nine years.

[5] Rate for 9-year period.

[6] Rate for 10-year period.

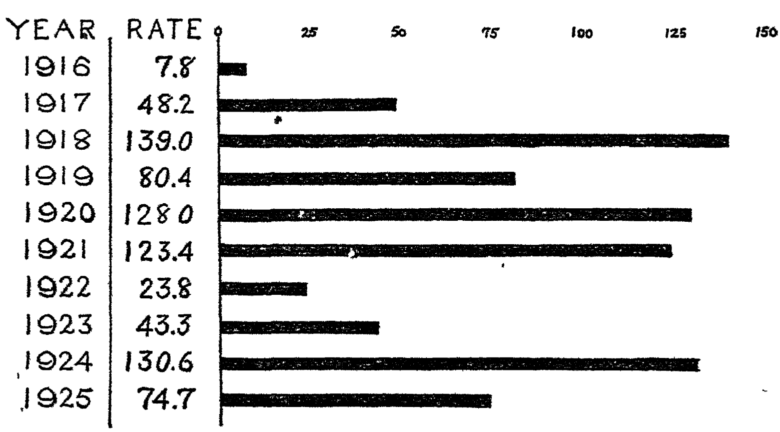
Incidence, 1920–1924.—Of 80 counties from which the data were obtainable, 67 reported 6,803 cases for the years 1920–1924, while 13 reported no cases. The largest number reported for any one county was 1,268; the median number reported was 27. Information was not obtainable in 11 counties, and for 4 no data are given.

Incidence in 1925.—Of 81 counties from which the information was obtained for 1925, 45 counties reported 969 cases of smallpox, the largest number for any one county being 200 cases, the median, 6 cases. Thirty-six counties reported no cases during the year.

Approximate number of vaccinations, 1920–1924.—In 73 of the counties for which information was available there were reported 110,932 vaccinations during the five years preceding the survey, the largest number for any one county being 15,000. The remaining 6 of these counties reported no vaccinations.

Cost of control measures, 1920–1924.—The total amount expended for medical service during the five-year period 1920–1924 for 38 of 50 counties for which information was available was given as $30,922.75, the largest expenditure for any one county being $7,600. The remaining 12 of these counties reported no expenses under this head.

SMALLPOX—TENNESSEE
Case Rate per 100,000



For special quarantine, 39 of 52 counties giving the information reported $13,399.18, the largest expenditure for any one county being $1,706. Thirteen of these counties reported no expenses under this heading. These expenditures are exclusive of the salaries of the health officers.

Difficulties met with in enforcement of vaccination.—The sentiment of county officials regarding compulsory vaccination as a condition for school attendance in the absence of an epidemic was fairly evenly divided. Lawsuits as a result of complusory vaccination were reported for three counties. Sectarian opposition to vaccination was said to exist in seven counties.

The following were among the difficulties most frequently met with by the health officers in the enforcement of vaccination:

1. Ignorance and exaggerated stories of bad results following vaccination.
2. Opposition aroused by enforcing quarantine regulations.
3. General opinion that the disease is mild and is less severe than the results of vaccination.
4. Lack of aggressive support by physicians.
5. Lack of support by officials of large industries.
6. Lack of financial aid by county officials.
7. Tendency and ability of certain classes to secrete the disease.
8. False conception of personal liberty
9. Opposition from certain religious sects.
10. Tendency of some local officials to suppress knowledge of outbreaks for commercial reasons.

RESULTS OF SURVEY

First-hand information was secured regarding the smallpox situation throughout Tennessee, the approximate number of immune persons, the cost of control measures, the sentiment of the county officials and the general population with regard to vaccination, and the difficulties most frequently encountered by health officers in the enforcement of vaccination regulations.

From an educational standpoint, the survey served to impress the gravity of the situation upon the local authorities and stimulated their interest. Although the expected increase in the incidence of smallpox over the previous year did not occur, had it occurred and had intensive control measures been necessary the educational work accomplished and the closer contact made between the State department and local health authorities would have greatly facilitated the enforcement of such measures.

CONCLUSIONS

Although the percentage of persons vaccinated in Tennessee is extremely low, it is believed that the State law empowering local boards to enact such vaccination measures as may be deemed necessary for the protection of the public is adequate for the time being. A State compulsory vaccination law, unenforceable in rural sections, might stir up such opposition as to hinder other health programs. By virtue of the present law, local officials have, in times of epidemics, enforced vaccination of contacts, of the inhabitants of a zone around the foci of infection, and of the school population with little or no opposition.

Greater reliance should, for the present, be placed on educational measures to secure more widespread vaccination. While the State health department should keep the local authorities informed and

make suitable recommendations from time to time. with a State the size of Tennessee the ultimate solution of this problem, as well as of many rural health problems, would seem to be in the extension of wholetime county health departments. Smallpox offers no serious problem to counties with such departments.

There seems to be a growing sentiment in the medical profession of the State, and especially among health officers, that quarantine measures are often ineffectual and that persons refusing vaccination on the grounds of restriction of personal liberty or otherwise should not be compelled to subject themselves to quarantine restriction. It is argued that such a course would emphasize the importance of vaccination and encourage its practice. Until, however, we can secure vaccination of all minors and irresponsible persons, until vaccination is an equal protection against the most severe as well as the milder forms of the disease, and until vaccination becomes an absolutely reliable procedure, with the use in every case of a vaccine of unquestionable potency and the most approved technique followed by a careful reading and an accurate interpretation of the result, the elimination of the strictest possible quarantine is inadvisable.

BENZOL POISONING AS AN INDUSTRIAL HAZARD

Review of Studies Conducted In Cooperation with the Subcommittee on Benzol of the Committee on Industrial Poisoning of the National Safety Council

By LEONARD GREENBURG, Associate Sanitary Engineer, Office of Industrial Hygiene and Sanitation, United States Public Health Service

VI. INTENSIVE STUDY OF SELECTED INDUSTRIES WITH RESPECT TO FACTORY CONDITIONS AND POLLUTION OF THE ATMOSPHERE BY BENZOL

A somewhat intensive study was made of a group of selected industries in which benzol was used, with a view to determining (*a*) the amount of benzol used and the precautions adopted in handling it, particularly the method of ventilation in force; (*b*) the resulting concentration of benzol in the atmosphere; and (*c*) the condition of the exposed workers as revealed by symptomatology and blood counts. The first of these studies were conducted during the summer of 1924, Mr. Dexter making the inspections and Doctor Shirley the clinical examinations. A second investigation was made during the winter of 1924–25, the writer making the inspections, and Doctor Shirley, Doctor Batchelor, and Doctor Herrman making the clinical examinations. The chemical tests were worked out and applied by the writer.

The first questionnaire as noted above gave a preliminary list of 84 firms using benzol. Later inquiries expanded this list to 104 organizations representing 125 different plants. Of these 125 plants our investigators actually visited 94, the remainder being omitted either because they were situated at too great a distance or because from what we could ascertain by correspondence they did not promise to prove useful for our purposes. Of the 94 plants visited, we were permitted to inspect 78, and from these 78 we ultimately selected 17 as suitable for intensive study. Five of these were later eliminated from consideration for various reaons, leaving 12 plants in which there was exposure of several or more workers to benzol vapors under conditions which might reasonably be expected to constitute a possible hazard: and in 18 different workrooms of these 12 plants detailed chemical and medical studies were made.

In each case the first step was to make a careful survey of existing conditions, using the inspection form reproduced below:

		Male	Female			

6 Fatigue

7 Remarks

It will be observed that under heading No. 1 certain fundamental structural data are listed. Heading 2 deals with the ventilation in use. Headings 3 and 4 deal with the fumes and vapors in the atmosphere and the shop conditions, which serve to bring about the presence of such vapors. The air sampling data were recorded under item 4 also.

Under heading 5 are grouped certain data which yield a rather general job analysis. Heading 6 provides for notes on fatigue, the purpose being an attempt to clarify the relation between heavy or light labor and the incidence of benzol poisoning. And, lastly, item 7 is for any remarks considered of value to the investigator and not provided for elsewhere In addition to filling out this form, the investigator prepared a series of notes on each of the plants studied, in greater detail than the form permits, and covering all those factors which may have had a bearing on the problem in hand.

In spite of the fact that benzol vapors have for a long time been associated with serious cases of acute and chronic poisoning, one finds on searching the literature of this subject that only a very small amount of work has been done on the actual concentrations of benzol vapor in plant atmospheres.

Harbeck and Lunge (102) showed that it was possible to recover benzol vapor quantitatively from air by absorption in a mixture of concentrated sulphuric and fuming nitric acids The benzol is, in this case, converted over to dinitrobenzol and is determined as such. Lehmann (103) tested this method with weighed quantities of benzol and obtained a recovery of 92 to 95 per cent. He also used this method with certain paraffin oil modifications and obtained yields of 94.4 to 100 per cent.

Using the method of nitrification for benzol determinations, Lehmann (3) found that 0.015 gram per liter (4,700 parts per million) produces listlessness and confusion after half an hour, and that 0.02 to 0 03 gram (6,260 to 9,390 parts per million) for a few hours may cause loss of consciousness. In this same contribution Lehman (3) quotes some of the earliest, if not the earliest, figures for the benzol concentration in factory air. He utilized the method of converting the benzol to dinitrobenzol as described earlier and found 0.080 to 0.094 milligram per liter (25 to 29 parts per million) in the air of a benzol washing plant, 0.11 to 0.16 milligram per liter (34 to 50 parts per million) in the air of a distillation plant, 0.19 to 0.34 milligram per liter (59 to 106 parts per million) at various stations in two benzol plants.

Albaugh (32) quotes the limits of toxicity of benzine, benzol, and turpentine as follows:

Benzine (naphtha, gasoline, petroleum benzine):
- 0.02 gram per liter (6,260 parts per million) causes local symptoms.
- 0.05 gram per liter (15,650 parts per million) is poisonous.

Benzol:

0 015 gram per liter (4,695 parts per million) is poisonous

0 042 gram per liter (13,146 parts per million) will kill dogs in 20 minutes.

Turpentine

0 003 gram per liter (919 parts per million) causes local symptoms.

0 006 gram per liter (1,878 parts per million) will poison healthy men in 1 to 4 hours

Albaugh does not cite the methods used for the determination of benzol or the source of these data.

Major Elliot and Captain Dalton (104), in studying the problem of the concentration of acetone, alcohol, and benzene in air, rejected the method based on nitration of the benzol with subsequent reduction, diazotisation, and combination with α naphthol to form a dye. This method was considered to be more complicated than Pfeiffer's method (105), and for this reason Pfeiffer's method was adopted Elliot and Dalton passed the air through 15 cubic centimeters of a mixture of equal volumes of fuming nitric acid and strong sulphuric acids. By further chemical procedures, dinitrobenzol was recovered and dissolved in alcohol, which was then heated with a solution of stannous chloride and the excess titrated with N/10 iodine, using starch as an indicator. They found a minimum of 0 01, an average of 0 26 and a maximum of 0.90 gram of benzene per million cubic centimeters of factory air. These figures, when converted, yield 3.1, 81.5, and 281 parts per million, respectively.

According to Hamilton (53), Pugliese (61) tested the air of the Milan raincoat factory in which three girl workers died from benzol poisoning one winter, and found that the air contained 1,000 parts of benzol per million. The method for the determination of benzol is not given. This quantity would, according to our experience, probably yield cases of benzol poisoning. Pugliese feels that by allowing sufficient space for each worker and ample ventilation, benzol poisoning should be easily avoided. He considered the conditions at the Pirelli works satisfactory, where each worker had over 1,500 cubic feet of space and over 1,600 cubic feet of forced air supply per minute.

Doctor Legge (54) cites the results of benzol determination made in the atmosphere of a balloon fabric spreading room. In this case the quantity of benzol vapor in the air ranged from 210 parts per million in the middle of a corridor opposite a machine to 1,050 parts per million in front of a fan between two spreading machines at work. In the pneumatic-tire manufacturing room analyses showed 2,800 parts per million with the windows open, whereas with the exhaust fan in operation a sample taken 18 inches from the work showed 800 parts per million. The method used for the determination of the benzol vapors is not given.

One of the most complete papers dealing with the determination of benzol with which the present investigators are familiar is that of Tausz (106). The work of this investigation, carried on purely from the point of view of the chemical determination of benzol in coke oven and illuminating gas, is valuable because of the very extensive review of methods for the determination of benzol presented therein. Practically every suggested method for the determination of benzol is reviewed in this paper and the author concludes that the method of activated charcoal is superior to all others. Using less than 1 cubic centimeter of benzol the author was able to obtain a yield of from 91 to 93 per cent, and this in a relatively short time and by simple analytical procedures.

In considering the methods for the determination of the benzol content of factory air the present investigation took into consideration all of the available literature, bearing in mind the fact that the method to be employed must be simple, the apparatus portable, and the analyses must be made in a comparatively short time. It was concluded that the activated charcoal procedure was the method of choice for the problem at hand. It is true that silica gel might have served the purpose; but with this substance it is necessary to use such precautions against the absorption of water vapor that it was decided not to use it Before finally selecting the charcoal method, its accuracy was determined by vaporizing a weighed quantity of benzol and determining the increase in weight of the tube of activated charcoal. In these experiments there was recovered an average of 92 per cent of the benzol introduced into the gas chain when sampling was conducted at the rate of 1 liter per minute. This means that the observed results are to be considered as approximately 8 to 10 per cent lower than the actual existing conditions. A difference of this amount is, however, not significant from the standpoint of this investigation. It is not a matter of whether there are 90 or 100 parts per million of benzol vapor in the air, but rather whether there are 50, 100, 200, 300, 500, 1,000, etc., parts per million present. When one bears in mind the fact that, under plant conditions, particularly in the summer season when windows are open and natural ventilation is good, the benzol vapor concentration in the workroom is subject to great and almost continuous variations, errors of 10 per cent are obviously of no serious significance.

Since activated charcoal also absorbs a certain amount of moisture, it was necessary to take suitable precautions to render the sampled air moisture-free before passing it into the charcoal absorption tube. The finished apparatus (shown in fig. 1) consisted of a carrying case, 14 by 15 by 15 inches, provided with a series of clamps for holding three tubes, the first two of which were 10 inches by 1 inch

Public Health Reports, Vol 41, No. 30, July 23, 1926

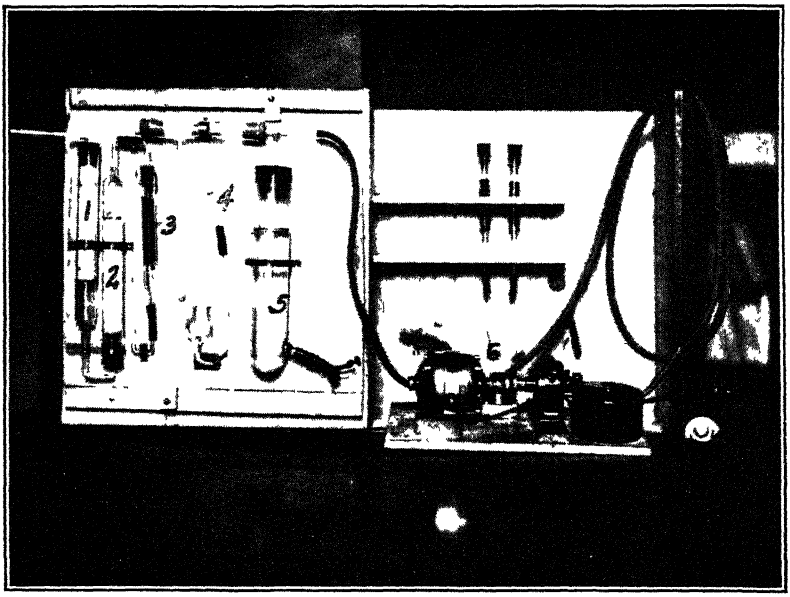

Fig 1 —Apparatus for sampling vapors in the air 1, Soda lime tube, 2, calcium chloride tube, 3, activated charcoal tube, 4, flow meter, 5, pressure regulator, 6, motor blower unit

and the last $6\frac{1}{2}$ inches by $\frac{5}{8}$ inch. The first tube was filled with soda lime for absorption of acid vapors, the second with calcium chloride for absorption of the water vapor, and the last tube with approximately 7 grams of 8 to 14 mesh activated charcoal.

Before filling the absorption tubes, the charcoal was dried over night in a constant temperature oven at 105° C. and kept in a tightly stoppered glass bottle. It was found advantageous to cover the retainer plate of the charcoal tubes with a piece of fine mesh copper gauze, which served to prevent any large grains of charcoal from falling through the plate. The tubes were then clamped in position beneath the stem of a small funnel, and the lower end of the tube was connected to a large bottle (7 liters capacity) by means of a piece of rubber tubing. The charcoal was then dropped, by means of a spatula, into the small funnel, from which it fell into the tube. After filling the tube in this manner, the stopcock between the tube and suction bottle was opened and closed several times. This procedure serves to remove the fines from charcoal tubes, which were never "tapped" during the process of filling. The foregoing method is the standard procedure recommended by the United States Bureau of Mines for the preparation of activated charcoal gas absorption tubes.

It was also found necessary to equilibrate the charcoal tubes before use This process consisted in connecting six charcoal tubes in parallel by means of a manifold made of glass tubing and connecting the manifold to the outlet side of the calcium-chloride tube. A tube of cotton wool was also added in the air chain in front of the soda-lime tube. Compressed air was then passed through the chain, which was composed of the following elements: Cotton-wool tube, soda-lime tube, calcium-chloride tube, manifold, and six charcoal tubes. The compressed air, at the rate of approximately 6 liters per minute, was allowed to flow through the chain of one and one-half to three hours, and on the completion of this step the charcoal tubes were desiccated over calcium chloride and later weighed. After the tubes were equilibrated in this manner it was found that the aspiration of ordinary room air through the sampling chain failed to produce any significant change in the weight of the charcoal tubes. Prior to going into the field, a sufficient number of charcoal tubes were prepared in the previously described method and placed in the rack of the carrying case provided for this purpose. At the selected point of the workroom the sampling apparatus was set up and the outlet end of the absorption tube connected to a 7-liter aspirator bottle, previously filled with water, which, when allowed to flow from the aspirator bottle, drew air through the gas chain. After a sufficient volume of air had been sampled, usually 20 liters, the charcoal tube was removed from the chain, stoppered at the top,

plugged at the bottom, and returned to the rack. On returning from the field the tubes were dusted with a camel's-hair brush, desiccated, and weighed, the increase in weight being taken to represent the approximate amount of solvent vapors in the atmosphere sampled. In those plants using benzol as the only solvent, this increase in weight represents that due to benzol vapors only.

It must be emphasized, however, that the method of analysis used is not specific for benzol, since the charcoal absorbs not only this substance but other solvent vapors as well. In the accompanying tables it is indicated whether other solvent vapors were present or not, and it will be noted that they were present in nine of the workrooms. In these instances, then, the figures for atmospheric pollution include all solvent vapors and not merely benzol, but since these tests were made chiefly as an index of the protection against atmospheric pollution by the ventilation equipment present, the results are believed to serve the purpose in a sufficiently satisfactory degree.

The general results of these studies on the extent of atmospheric pollution in workroom air are presented in Table 4. They cover 18 different workrooms which are fairly representative of the various processes in which benzol is used in the rubber, patent leather, and artificial-leather industries, in wire insulating, dry cleaning, and sanitary-can manufacture. Of the 18 workrooms, 9 were provided with no artificial ventilation, 4 were equipped with local exhaust ventilation, 2 with general room ventilation, 1 with both local exhaust and general ventilation, and 2 with what amounted practically to an inclosed process. In two instances (room 27A and room 75B) but one determination was made in each workroom in summer. The other summer averages are generally based on two or three determinations. Summer records in room 75A and in plants 83 and 150, as well as all the winter records, are based on the average of 10 to 20 determinations.

It has been pointed out above that the absorption method used in this investigation for the determination of benzol fails to distinguish between benzol and other solvent vapors, such as alcohol, methyl acetone, ethyl acetate, and the like. For the purpose of studying the efficiency of ventilation, however, the total concentration of solvent vapors is entirely satisfactory, and it is indicated in the table whether such other vapors were present in addition to benzol. The figures for solvent vapors are, however, all computed in terms of benzol.

[1] O=none, G=general room ventilation, L=local exhaust ventilation, E=inclosed process. Examinations were made of as many workers as possible. Air samples represent conditions of the general room air and of the air at the station of the worker. All samples were taken at the breathing level.

It will be noted that a wide variation in concentration of solvent vapors was observed, ranging from 0 to 4,140 parts of benzol per million parts of air. In six instances comparable data for winter and summer conditions were secured. In rooms 59, 61A, 75A, 78A, and 91 the winter figures are from 25 to 100 per cent higher than those obtained in summer, as one might naturally expect from the effect of decreased ventilation. In the case of room 61B the summer figures are higher than the winter figures because a hot mixing process, which was going on when the summer samples were taken, had been abandoned in the winter.

A better idea of the significance of the results may be obtained by reference to Table 5, in which the average results of the air analyses are grouped according to the amount of solvent used and the character of the ventilation devices installed.

TABLE 5.—*Atmospheric concentration of solvent vapors in relation to amount of solvent used and ventilation procedures*

Group	Workroom	Gallons of benzol used per week	Ventilation	Average solvent vapors in air (p. p. m.)	
				Summer	Winter
I Small amount of benzol used; no local ventilation.	150B	50	None	100

III Large amount of benzol used, no local ventilation.	95	500	General	1,800	
	78B	750	None	340	
	23	4,200	None	220	
	83	10,000	None	620	

Group I includes seven workrooms, each using 300 gallons of benzol a week or less—one, 27B, provided with a system of general ventilation, the remainder with no artificial ventilation. In spite of the small amount of solvent used, the concentration of benzol vapors in the air was very high in the case of room 27B. Slickering of hides was the process carried out in this room, and the ventilation consisted only of general exhaust fans without hoods. This result (coupled with the data for room 95) confirms the opinion that this type of ventilation is distinctly unreliable. In the other six workrooms of this group there was no provision for artificial ventilation. In spite of this fact the benzol concentration in the air of five of the rooms (150B, 60, 27A, 59, and 61A) was fairly low in summer; but of those examined in winter (59 and 61A), both showed over 200 parts per million of solvent vapors. In rooms 60, 27A, and 61B the operation was a mixing process in which the extent of atmospheric contamination would naturally be less than in the case of cementing (150B), tire making (59), and insulating wire (61A). All that can be deduced from these figures is that, while the use of small amounts of benzol without ventilation may happen often to be associated with low benzol concentration in the air, such processes, even when confined to mixing, may at other times, particularly in winter, show marked atmospheric contamination.

Group II is of particular interest. Here are seven workrooms using from 450 to 4,200 gallons of benzol per week, all provided with systems of local ventilation (or, in the case of rooms 50B and 75B, with what were practically inclosed processes). Room 91 (in a sanitary-can plant) showed high benzol figures even in summer. This room had a good local exhaust from the ovens, but the temperature of the ovens was too low for the speed at which the can ends

passed through, so that the warm metal still gave off much benzol vapor after it emerged. These hot can ends were permitted to accumulate in large numbers in the room, and largely to this cause is attributed the high benzol concentration noted in the air Room 75A was fairly low in benzol content in summer (130 parts per million), but high in winter (330 parts per million). This is a coating room with an exhaust ventilation system which our observer reported to be improperly arranged and in which the air was subject to additional pollution from the coated cloth which was allowed to cool in the room after passage through a hot chamber Rooms 50A and 50B were examined only in winter and showed high benzol contents (500 and 430 parts per million). In room 50A, four machines for coating artificial-leather were provided with exhausts, while a fifth was not. In room 50B benzol was used in supposedly inclosed mixers, but maintenance was poor and much solvent was allowed to evaporate from open receptacles. Room 150A was a rubber coating room with local ventilation, but so operated as to threaten considerable atmospheric contamination; and room 75B was a mixing room in an artificial-leather factory. Both showed low benzol concentrations in summer but, unfortunately, they were not studied in winter. Finally, room 78A was a lining room in a sanitary-can factory with excellent local exhaust ventilation, in which summer analyses gave an average of 70 parts per million of benzol, and winter analyses (18 in number) an average of 90 parts per million. These last three plants, and particularly 78A, show what excellent results may occasionally be accomplished by local ventilation in the use of benzol.

Finally, group III consists of four plants using 500 to 10,000 gallons of benzol a week without local ventilation. Room 95, a dry-cleaning room, with general ventilation only, showed the highest average (1,800 parts per million) and the highest maximum (4,140 parts per million) benzol content revealed in the entire study. In all the other three cases the atmospheric contamination was also high, even though two of the rooms (78B and 83) were used only for mixing processes.

In general, it may be concluded from these studies of workroom air that rooms in which benzol is evaporated into the air without local exhaust ventilation will, in most cases, show high concentration of the fumes in the air of the rooms Where the amount of benzol used was small, this was sometimes not apparent in our analyses (rooms 150B, 60, and 27A); but in room 60 only two analyses were made and in 27A only one analysis was made. Mixing processes were carried on in both rooms.

With ideal local exhaust ventilation, on the other hand, even large quantities of benzol can be used without heavy atmospheric contamination (78A, lining; 150A, coating; and 75B, mixing).

VII. RESULTS OF MEDICAL EXAMINATION AND CLINICAL TESTS MADE TO DISCOVER EARLY SIGNS OF BENZOL POISONING IN EXPOSED WORKERS

The examination of workers exposed to various concentrations of benzol in the atmosphere with a view to the determination of the extent of the existing hazard, is the crucial part of the investigation.

It is obvious that the symptoms of chronic benzol poisoning are such as to be frequently overlooked in the absence of careful and systematic medical examinations and the 98 cases of poisoning reported by the industries studied must greatly understate the case. Fortunately we have in the blood picture an excellent test for the detection of poisoning in its very early stages, and chief stress has been laid upon this point in our studies. Altogether it was found possible to make blood tests on 81 different individuals exposed to the influence of benzol in the 18 workrooms studied.

Wherever possible, general physical examinations were also made and medical histories obtained of the workers in question; but in many instances this could not be done. For recording the data obtained in the history and physical examination, the form reproduced below was used. It will be observed that certain plant and occupational data are first called for, followed by a list of the symptoms most commonly found to be of significance in the patient's history. The reverse side of the card was used for the findings of the medical examiner, laboratory notes, and personal and family data. This card was found to be very well suited to the purpose in hand.

As pointed out in the foregoing pages of this report, the change in the white blood cell count is by far the most important early sign of benzol poisoning. Normally, in health, the white blood cell count varies between 7,500 and 9,000 per cubic millimeter. As a lower limit in health, the figure 7,500 may be taken. In chronic benzol poisoning the count is reduced often much below this point and may reach an exceedingly low figure. In one case in the present investigation, in which the man remained at work, and his count was obtained while the usual routine study was being made, the white blood cell count was depressed to below 2,000. In attempting to fix on some definite standard for the white cell count which would, along with a history of exposure, be indicative of benzol poisoning, we decided that a fall of 25 per cent below the lower limit of the normal count of 7,500 (i. e., to 5,625) might be accepted as reasonably clear evidence of the condition in question. The interpretation of the blood picture was, however, not based solely on the total white cell count. Chronic benzol poisoning produces also a marked change in the relationship between the various types of white blood cells present. Ordinarily the polymorphonuclear white cells comprise between 65 and 70 per cent of all of the white blood cells, whereas the lymphocytes comprise but 20 to 30 per cent. In benzol poisoning the percentage of lymphocytes is relatively increased and that of the

polymorphonuclear leucocytes is markedly decreased. In making a diagnosis of benzol poisoning these aspects of the differential count were carefully considered.

This study had for its primary aim the correlation of the quantity of benzol vapor in the air with the clinical findings produced by the inhalation of this quantity of benzol That such a correlation as this is not easily obtained was proved early in the course of the study. The quantity of benzol used in any plant may vary between very wide limits at different seasons of the year, and, moreover, in any given establishment the winter and summer concentrations of benzol may be, and, in most cases, are, widely different. An attempt was made, however, to overcome this condition by sampling the room air both in the winter and summer season wherever this was possible. The duration of exposure, too, has its obvious bearing on the problem; and in this connection it is advisable to reiterate that a marked variation in personal susceptibility to benzol poisoning exists. It was found, for example, that of many persons employed for equal periods of time in a plant using benzol, only a few will be found clearly positive; while in other plants the persons who are positive for benzol poisoning may have worked in the industry for a shorter period of time than those who are negative.

In the summer of 1924 blood tests were made on 84 different workers, but 56 of these operatives while in plants using benzol were not exposed to a degree which would lead one to expect anything but the negative results actually obtained. These 56 tests have, therefore, been excluded from further consideration, leaving 28 tests made on exposed workers during this period. In the winter of 1924-25, 53 more such tests were made, giving a total of 81 in all.

In Table 6 is presented a summary of these findings for the 18 workrooms studied, arranged in groups according to the amount of benzol used, the ventilation equipment, and the analytical results obtained.

[a] 3 clinical cases, 1 fatal, since tests were made

In making a presumptive diagnosis on the basis of the blood examinations only those cases were considered positive which showed less than 5,500 white cells per cubic millimeter (as compared with a normal count of 7,500 to 9,000), except in a single instance (room 150B), where a female cement worker with a border-line white-cell count of 5,800 was considered positive because of an exceedingly low red-cell count (2,800,000 red cells per cubic millimeter, hemoglobin 49 per cent of normal). Many other individuals examined showed white-cell counts between 5,500 and 6,000, which would ordinarily be considered as suspicious, but were omitted and only the clearly outstanding cases were considered positive.

From Table 7 it will be seen that 10 out of the 26 cases considered positive had a white-cell count below 4,000. The red-cell count we find less strikingly reduced than the white-cell count, only 10 of the cases being below 4,000,000. This is, of course, to be expected, since the red-cell count is usually affected considerably later than the white-cell count in the development of chronic benzol poisoning. In the early stages of this disease an abnormal stimulation of red-cell production may, indeed, sometimes be noted.

More detailed data in regard to the blood picture of 13 of the cases considered as characteristic of early benzol poisoning are presented in Table 8, which indicates the constant reduction of total white cells, the relatively increased proportion of lymphocytes, the reduction in hemoglobin, and the common, but not universal, reduction in red cell count.

Figures for normal male and female blood counts are cited for comparison.

It may be of some interest to present in some detail one or two cases of benzol poisoning which have come to our attention during the course of this study.

Case S. C.: A tire builder in a rubber-tire factory. Entered hospital May 20, 1924, with a complaint of weakness, dizziness, slight cough with shortness of breath, and palpitation. During three weeks prior to hospital entry, patient developed bleeding gums and severe nosebleeding. "Loss of ambition" and "sleepiness" were also stressed by the patient. Physical examination revealed pallor, pale gums with gingivitis, and fading brownish purpuric spots on thighs; the essential findings on study of this case were as follows:

Blood studies showed Hb., 30 per cent, R. B. C., 1,200,000; color index, 1.2; W. B. C., 1,800; platelets, 45,000.

Blood smear: Size and shape of red cells markedly uniform and regular for such a severe anemia A few fragmented cells and a rare poikilocyte is seen. Slight polychromatophilia.

Gastric analysis, test meal. Total acidity, 56 per cent; free HCl, 26. A diagnosis of aplastic anemia, due to chronic benzol poisoning, was made.

Patient remained in hospital for five weeks. Had slight bleeding from gums after admission Received two blood transfusions with marked symptomatic improvement. Discharged June 25, 1924, condition improved; to return for later transfusion. Blood count at discharge showed R. B. C. 2,280,000, Hb 45 per cent, W. B C, 1,800.

Case J. C. A worker in a wire-insulating establishment; entered the hospital on May 18, 1924, complaining of progressive weakness for the past three months, with severe nosebleed, gastric disturbances, dyspnea, palpitation. Increasing pallor and yellowness of skin were observed by the patient. Neurological symptoms were lacking. A similar although milder attack was suffered by the patient about four years earlier while he was employed in the same factory.

Physical examination revealed only the presence of a distinct lemon yellow colored skin and hyperactive reflexes. The blood examination disclosed a negative Wassermann reaction. A diagnosis of chronic aplastic anemia, due to chronic benzol poisoning, was made. The chronological history of this patient's blood follows:

Date	R B C	Hb	W B C	Polys	Lymph	Remarks
		Per cent				
Mar 21, 1924	680,000	25	1,100	40	55	
Mar 22, 1924	1,120,000	25				1½ hours post transfusion
Apr. 3, 1924	1,296,000	35	1,150			
Apr 5, 1924	1,520,000	40	1,350			20 hours post transfusion
May 2, 1924	1,600,000	30	1,600	32	60	
May 7, 1924	1,760,000	40	1,400	60	39	Post transfusion
May 17, 1924	2,112,000	40	1,800	47	49	

The patient was discharged after spending 57 days in the hospital and was ordered to remain away from the benzol atmosphere and to return to the clinic from time to time for examination.

It was found possible to obtain detailed clinical histories for only 9 out of the 26 individuals showing a blood picture characteristic of early benzol poisoning. The results are presented in Table 9.

TABLE 9.—*Symptomatology and physical findings on nine cases of early benzol poisoning*

Findings	Case 1	2	3	4	5	6	7	8	9	Total
Loss of appetite								+	+	2
Gastric disturbance								+		1
Constipation	+									1
Headache				+					+	2
Dizziness	+			+	+				+	4
Nosebleed								+		1
Pallor	+	+			+	+	+		+	6
Spongy gums					+				+	2
Poor nutrition					+					1

Pallor and dizziness were the most common symptoms, and five of the nine cases showed groups of symptoms which, on a careful medical inquiry, might have aroused suspicion of poisoning (case 1—constipation, dizziness, pallor, case 4—headache, dizziness, case 5—dizziness, pallor, spongy gums, poor nutrition, case 8—loss of appetite, gastric disturbance, nosebleed, case 9—loss of appetite, headache, dizziness, pallor, spongy gums). In general, however, the chief result of the examination of this small group of cases is to indicate that benzol poisoning may proceed for a considerable length of time and may produce marked changes in the blood-cell count of the patient without leading to any symptoms obvious enough to indicate to the patient that anything is wrong. Yet the relation discussed in a preceding section between low blood counts and susceptibility to microbic infection clearly indicates how serious such a condition may be.

Considering, then, the most important index of early benzol poisoning—reduction in the white-cell count—the results obtained (as indicated in Table 6) are distinctly disconcerting. In Group IA, which includes plants using small amounts of benzol and showing reasonably low concentrations of benzol in the air in summer, although lacking any provision for local exhaust ventilation, 3 out of 12 men examined showed the blood picture of chronic benzol poisoning. In Group IB, which includes rooms with small amounts of benzol in use, but without local exhaust ventilation, and showing high benzol concentration in the air, 8 out of 24 men examined gave positive results.

In Group IIB, with large amounts of benzol in use, and with local ventilation systems proved inefficient by high analytical results, 3 men out of 22 gave a blood picture characteristic of benzol poisoning; while in Group III, where large amounts of benzol were used without exhaust ventilation and with high contamination of the air, 10 out of 19 workers gave positive results.

There remains for special consideration Group IIA, which should furnish the crucial test of the benzol hazard under the most favorable possible conditions. Here large amounts of benzol were used, but with local exhaust systems so efficient that our records show averages of 105 parts per million or less. It is most unfortunate that we were unable, after repeated efforts, to secure permission to make blood examinations in room 78A (a sanitary can factory). In room 150A (a coating room) there was only one worker exposed to the fumes. He was positive, with a white count which fell progressively from 9,300 in October, 1924, to 5,500 in May, 1925, and to 4,700 in July, 1925. His red count remained over 4,000.000. In room 75B three men were exposed to benzol fumes (only 105 parts per million

of benzol in the air, as a result of excellent exhaust ventilation); but one of the three proved positive, with a white-cell count of 4,250 and a red count of 4,260,000 Even with exhaust ventilation of a good type giving average atmospheric benzol concentrations of less than 100 parts per million, the hazard from the use of benzol is evidently not entirely removed. Furthermore, our studies indicate that such excellent systems of ventilation are rare. Under the conditions in which benzol is actually used in industry to-day we have found that out of a total of 81 exposed workers examined, 26 showed a blood picture so characteristic as strongly to suggest benzol poisoning We are forced to conclude that the use of benzol (except in inclosed mechanical systems), even when the workers are protected by the most complete and effective systems of exhaust ventilation, keeping the average concentration of benzol in the workroom air below 100 parts per million, involves a substantial hazard Every possible effort should, therefore, be made to develop the use of substitute solvents of a less toxic nature wherever this is possible.

CONCLUSIONS IN REGARD TO THE USE OF BENZOL IN INCLOSED SYSTEMS

As pointed out above, benzol is used in industry under two more or less distinct sets of conditions. In the manufacture of benzol from coal and coal tar, in the blending of motor fuels, and in the chemical industries the solvent is necessarily handled in closed containers and pipe systems. Here chronic poisoning is unlikely to occur and the chief hazard arises from acute poisoning due to carelessness in the cleaning of tanks, breaks in the apparatus, and similar accidents.

With regard to this type of process it seems certain that with proper care in construction, maintenance, and operation, the use of benzol can be made sufficiently safe to warrant its employment. It is true that fatal accidents have occurred, and will no doubt continue to occur, in such processes, just as such accidents occur, and will continue to occur, from the use of steam boilers. The danger is, however, in both instances a controllable one, to be met by careful attention to safety provisions and not by the abandonment of the use of the substance or device in question.

The chief measures of protection which should be enforced in industries of this type are—

(*a*) Regular and systematic inspection of apparatus to insure against breaks or accidental leakage.

(*b*) The greatest possible care in freeing tanks or other receptacles which have contained benzol from all traces of the substance before they are entered for cleansing or repairing.

(c) The protection of workers entering inclosed spaces likely to contain benzol fumes by the use of positive pressure air helmets or hose masks; and the conduct of all such work by teams of two or more men who are familiar with the dangers involved.

CONCLUSIONS IN REGARD TO THE USE OF BENZOL AS A SOLVENT

In the rubber industry, in artificial-leather manufacture, in sanitary-can manufacture, in dry cleaning, and in the use of paints and varnishes benzol is employed as a solvent or vehicle under conditions which, almost of necessity, permit more or less evaporation of the solvent into the atmosphere. Here there is relatively little danger of acute benzol poisoning but very great danger of chronic poisoning, arising from prolonged or repeated exposure to the fumes.

In order to minimize such hazards as far as possible, there are two general types of precautions which should be taken, tending, (1) to decrease the degree of exposure and (2) to detect and control incipient poisoning in its earliest possible stages.

(1) To diminish exposure, inclosed processes should, of course, be used wherever possible, and whenever containers are cleaned or apparatus repaired the special precautions discussed in the preceding paragraph dealing with acute poisoning should be observed. Wherever employees are likely in the course of their work to be exposed to benzol fumes, as in the ordinary solvent and evaporative processes or in handling the products of such processes, they should be protected by the most effective local exhaust ventilation designed according to the following general principles:

(a) Where benzol is evaporated at room temperatures air removal by local exhaust ventilation with down draft is recommended, although in certain inclosed processes direct ventilation (from the inclosure) with upward draft may be indicated.

(b) Where localized heat is applied in the evaporation of the benzol, hoods or inclosures should be provided with up-draft local exhaust. This draft should be sufficiently intensive and applied so closely to the point of origin of the evaporating benzol as to insure the complete removal of all of the benzol before the heated surface is removed from the hood or inclosure. This recommendation deals with specific processes where sufficient upward air movement is created by the heated surface to overcome the natural density of the benzol vapor.

Masks and respirators should not be relied upon to protect the worker against ordinary routine exposure to benzol fumes, since such devices can not be made efficient without at the same time making them too uncomfortable to be worn continuously.

(2) To detect incipient benzol poisoning at a stage when its effects can be minimized, it seems essential to the committee that all work-

ers to be employed in processes where exposure to the fumes of this solvent is involved, should be given a thorough medical examination before employment, and reexamined, with systematic blood counts, once a month thereafter. In addition to this routine reexamination absence from work should be promptly followed up by some person conversant with the symptoms of benzol poisoning and the employees themselves should be made familiar with the symptoms which are most likely to occur.

No worker should be employed in a benzol process who shows signs of—

(*a*) Organic disease of heart, lungs, or kidneys.
(*b*) Hemorrhagic tendencies.
(*c*) Anemia or any unusual blood picture

Any worker who, on reexamination, shows any of the following symptoms should be promptly excluded from benzol exposure and transferred to some other department of the industry

(*a*) Hemorrhages from the mucous membranes of the nose, mouth, or other organs.
(*b*) Decrease of more than the following from the employee's normal blood picture (normal conditions to be obtained from previous examinations of the individual employee)—
  (1) White cells: Decrease of 25 per cent; but in no case should an employee with a white cell count of less than 5,000 be continued in benzol processes.
  (2) Red cells: Decrease of 25 per cent.
  (3) Hemoglobin: Below 70 per cent.

(NOTE.—Reduction in white cells is the most important condition to be noted.)

PUBLIC HEALTH ENGINEERING ABSTRACTS

Recent studies relating to the purification of water and the action of various waters on lead and copper pipes.—John C Thresh and John F. Beale *Surveyor*, vol 68, No 1771, December 25, 1925, pp. 579–580. (Abstract by Rudolph E Thompson.)

Excess lime treatment.—Data derived from the operation of a 25,000-gallon experimental plant in connection with the proposed supply of Southend Water Co , from the Rivers Chelmer and Blackwater are given The purification process consisted of excess lime treatment, recarbonation, and rapid sand filtration. Sufficient lime was added to maintain an excess of 10 p p. m. after 24 hours, the process being controlled by the reaction of the treated water to brilliant cresyl blue. With this excess the total number of bacteria was reduced from thousands to units, *B coli* was invariably absent in 100 c. c. quantities, color of treated water was less than 10 American Public Health Association units, and organic matter was reduced 50 per cent. Lime in the form of lime water was found to be more efficient and economical than milk of lime The addition, prior to adding the lime, of 1 gr. of aluminum sulphate per gallon was found necessary for rapid precipitation and color removal.

B. coli as an index of fecal contamination.—Contamination by birds and fish does not adequately explain the abundance of *B. coli* in certain stored waters, compared with the complete disappearance of this organism in water stored under laboratory conditions. In a recent investigation *B. coli* was found to flourish in the presence of the weed *Enteromorpha intestinalis*, which is usually found in brackish water but which in this case was growing abundantly in reservoir and filter beds Similar multiplication occurred in presence of *Oscillatoria nigra.* Decaying weeds have been found to give rise to an enormous increase in *B. aerogenes.* These results indicate that presence of *B. coli* is not always evidence of manurial pollution.

DEATH RATES IN A GROUP OF INSURED PERSONS

Rates for Principal Causes of Death for May, 1926

The accompanying table is taken from the Statistical Bulletin for June, 1926, published by the Metropolitan Life Insurance Co., and presents the mortality experience of the industrial insurance department of the company for May, 1926, as compared with April, 1926, and with May and year, 1925. The rates are based on a strength of approximately 17,000,000 insured persons in the industrial populations of the United States and Canada.

The Bulletin states:

The death rate * * * during May (9.1 per 1,000) was substantially the same as reported for that month in 1925. Pronounced increases over last year's May figures were registered in the mortality from measles, whooping cough, influenza, and pneumonia; but these increases were about compensated by lower rates for diphtheria, tuberculosis, diarrheal diseases, and accidents. The May death rate was the lowest recorded for any month of 1926, and the decline of 24.2 per cent as compared with April is rather in excess of the seasonal drop expected at this time of the year. The outstanding factors in the decline from the April figure were lower death rates for influenza and pneumonia, the mortality from these diseases declining 57.8 per cent and 43.2 per cent, respectively.

Although the measles rate dropped from 21.3 per 100,000 in April, to 16.6 in May, and the whooping cough figure from 15.4 to 11, the May rates are still inordinately high for these two maladies, which the average citizen is wont to regard as of minor importance when compared with diphtheria and scarlet fever. Present-day mortality statistics of these diseases of childhood present a striking contrast to those of a few years ago. In this connection comparison of the table with a similar table for May, 1920, discloses a diphtheria rate of 16.2 per 100,000, which was much higher than the figure then shown for measles, and two and one-half times as high as the whooping cough death rate then recorded, despite the fact that 1920 was a year of above-average mortality from both measles and whooping cough. In May, 1926, on the other hand, we find measles to be the leader among the diseases of childhood, causing approximately twice as many deaths as diphtheria. Whooping cough is now second in importance with a much higher death rate than diphtheria and is charged with three and one-half deaths to every one from scarlet fever. While it is true that 1926, to date, has been a year of above-average prevalence of measles and whooping cough, it bids fair to mark a new minimum death rate for what has always been the most dreaded of the diseases of childhood; that is, diphtheria.

Death rates (annual basis) for principal causes per 100,000 lives exposed, April and May, 1926, and May and year, 1925

Cause of death	Death rate per 100,000 lives exposed [1]			
	May, 1926	April, 1926	May, 1925	Year 1925 [2]
Total, all causes	913.8	1,199.4	901.1	906.9
Typhoid fever	1.8	2.5	2.0	4.6
Measles	16.6	21.3	5.1	3.3
Scarlet fever	3.4	5.1	4.7	3.5
Whooping cough	11.0	15.4	8.1	7.7
Diphtheria	8.6	9.0	10.6	10.6
Influenza	38.5	91.3	25.5	21.9
Tuberculosis (all forms)	98.8	114.9	104.5	98.0
Tuberculosis of respiratory system	86.4	99.5	89.3	85.8
Cancer	65.5	77.1	67.2	70.5
Diabetes mellitus	14.0	20.1	14.1	15.2
Cerebral hemorrhage	50.2	61.3	50.6	53.7
Organic diseases of heart	126.6	171.8	126.7	126.6
Pneumonia (all forms)	108.4	191.0	96.5	86.5
Other respiratory diseases	12.5	19.6	14.5	13.3
Diarrhea and enteritis	15.4	17.8	19.4	36.6
Bright's disease (chronic nephritis)	69.6	82.6	68.0	69.8
Puerperal state	15.2	17.9	15.7	16.5
Suicides	7.8	7.6	5.4	6.9
Homicides	5.9	7.6	6.9	7.2
Other external causes (excluding suicides and homicides)	53.6	53.1	56.7	64.2
Traumatism by automobiles	14.9	13.5	14.4	16.5
All other causes	190.6	212.6	198.8	190.5

[1] All figures include infants insured under 1 year of age.
[2] Based on provisional estimate of lives exposed to risk in 1925.

DEATHS DURING WEEK ENDED JULY 10, 1926

Summary of information received by telegraph from industrial insurance companies for week ended July 10, 1926, and corresponding week of 1925 (From the Weekly Health Index, July 14, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended July 10, 1926	Corresponding week, 1925
Policies in force	64,650,237	60,488,896
Number of death claims	8,898	9,399
Death claims per 1,000 policies in force, annual rate	7.2	8.1

Deaths from all causes in certain large cities of the United States during the week ended July 10, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, July 14, 1926, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population.
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Data for 62 cities.
[4] Deaths for week ended Friday, July 9, 1926.
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population. Atlanta 31, Baltimore 15, Birmingham 39, Dallas 15, Fort Worth 14, Houston 25, Kansas City, Kans., 14, Louisville 17, Memphis 38, Nashville 30, New Orleans 26, Norfolk 38, Richmond 32, and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

PLAGUE-ERADICATIVE MEASURES IN LOS ANGELES, CALIF.

The following items were taken from the reports of plague-eradicative measures from Los Angeles, Calif.:

June 21 to June 29, 1926

Number of rats trapped	3[illegible]9
Number of rats found to be plague infected	0
Number of squirrels examined	1,371
Number of squirrels found to be plague infected	0
Number of mice trapped	191
Number of mice found to be plague infected	0

Date of discovery of last plague infected rodent, November 6, 1925

Date of last human case, January 15, 1925

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended July 3, 1926, 37 States reported 934 cases of diphtheria For the week ended July 4, 1925, the same States reported 814 cases of this disease Ninety-nine cities, situated in all parts of the country and having an aggregate population of more than 30,350,000, reported 711 cases of diphtheria for the week ended July 3, 1926. Last year, for the corresponding week, they reported 515 cases. The estimated expectancy for these cities was 716 cases The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-four States reported 6,941 cases of measles for the week ended July 3, 1926, and 2,169 cases of this disease for the week ended July 4, 1925. Ninety-nine cities reported 2,483 cases of measles for the week this year and 1,259 cases last year.

Poliomyelitis.—The health officers of 38 States reported 27 cases of poliomyelitis for the week ended July 3, 1926. The same States reported 68 cases for the week ended July 4, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 1,802 cases; last year, 1,052 cases; 99 cities—this year, 985 cases; last year, 524 cases; estimated expectancy, 487 cases.

Smallpox.—For the week ended July 3, 1926, 38 States reported 424 cases of smallpox. Last year for the corresponding week they reported 331 cases. Ninety-nine cities reported smallpox for the week as follows: 1926, 63 cases; 1925, 78 cases; estimated expectancy, 71 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—Four hundred and fifty-two cases of typhoid fever were reported for the week ended July 3, 1926, by 36 States. For the corresponding week of 1925 the same States reported 784 cases of this disease Ninety-nine cities reported 94 cases of typhoid fever for the week this year and 193 cases for the corresponding week last year. The estimated expectancy for these cities was 119 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 94 cities, with a population of more than 29,650,000, as follows: 1926, 461 deaths, 1925, 332 deaths.

City reports for week ended July 3, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to acertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[1] Rabies in man—1 death at Pittsburgh, Pa.
[2] Dengue—1 case, Charleston, S. C.

The following table gives the rates per 100,000 population for 103 cities for the five-week period ended July 3, 1926, compared with those for a like period ended July 4, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 103 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, May 31 to July 3, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

British India.—Chittagong, Cochin, Tuticorin, Vizagapatam

Federated Malay States.—Port Swettenham.

Straits Settlements.—Penang, Singapore

Dutch East Indies.—Batavia, Samarang, Cheribon, Belawan Deli, Palembang, Sabang, Macassar, Menado, Balik-Papan, Padang

Sarawak Kuching.

British North Borneo.—Sandakan

Portuguese Timor.—Dilly

Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.

French Indo-China.—Turane

China.—Shanghai, Hong Kong.

Formosa.—Keelung.

Japan.—Nagasaki, Yokohama, Moji, Kobe, Niigata, Tsuruga, Hakodate, Shimonoseki.

Korea.—Chemulpo, Fusan.

Manchuria.—Antung, Mukden, Changchun, Harbin.

U. S. S. R.—*Vladivostok*.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.
New Guinea—Port Moresby
New Zealand—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia.—Noumea
Hawaii—Honolulu.

AFRICA

Egypt.—Alexandria, Port Said, Suez.
Anglo-Egyptian Sudan—Port Sudan.
Eritrea—Massaua.
French Somaliland—Jibuti.
British Somaliland—Berbera
Italian Somaliland—Magadiscio.
Kenya—Mombasa
Zanzibar.—Zanzibar
Tanganyika.—Dar-es-Salaam.
Seychelles—Victoria
Madagascar—Tamatave
Portuquese East Africa—Mozambique, Beira, Lorenço Marques.
Union of South Africa—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from:

British India—Calcutta
Dutch East Indies—Banjermasin, Tarakan, Pontianak.
Mauritius.—Port Louis

SMALLPOX ON VESSEL

At Aden, Arabia.—Under date of June 12, 1926, four cases of smallpox with one fatality were reported at Aden, Arabia. The cases were stated to have been imported by sea.

BRAZIL

Mortality—Smallpox—Disease prevalence—Manaos—April, 1926.—During the month of April, 1926, 156 deaths from all causes were reported at Manaos, Brazil including measles 1 death, smallpox 5, tuberculosis 22, bronchial affections 6, intestinal disease 25, and malaria 25 deaths.

Yellow fever.—Information received under date of June 26, 1926, relative to the yellow fever situation in Brazil states that there were no reported cases in any of the large coast cities, and that the water fronts were safe. Cases of yellow fever were reported from various places in the interior of Bahia, Pirapora, and Minas. Mosquito indices appeared to be safe except at Maranhao.

CANADA

Communicable diseases—Province of Ontario—April 26–May 29, 1926—Comparative.—During the period April 26 to May 29, 1926, communicable diseases were reported in the Province of Ontario, as follows:

Disease	1926		1925	
	Cases	Deaths	Cases	Deaths
Cerebrospinal meningitis				3
Chancroid	1			
Chicken pox	423		363	
Diphtheria	145	8	193	10
German measles	690		21	
Gonorrhea	117		215	
Influenza		30		28
Lethargic encephalitis		2		2
Measles	2,962	2	2,152	
Mumps	157		478	
Pneumonia		232		108
Poliomyelitis	1		5	2
Scarlet fever	501	6	507	6
Septic sore throat			2	
Smallpox	51	1	16	1
Syphilis	133		177	
Tuberculosis	201	84	209	92
Typhoid fever	32		53	9
Whooping cough	321	10	400	11

Smallpox.—Smallpox was reported at 16 localities, with the greatest number of cases, viz, 10, at Pakenham. At Orillia and Toronto 7 cases each were reported; at Waterloo, 6 cases, at Sarnia 4 cases, at Kitchener 3 with 1 death.

EGYPT

Plague—June 4–10, 1926—Summary.—During the week ended June 10, 1926, 5 cases of plague were reported in Egypt, making a total from January 1 to June 10, 1926, of 56 cases of plague, as compared with 64 cases reported during the corresponding period of the preceding year. Of the 5 cases reported for the week ended June 10, 2 cases occurred at Suez.

ESTHONIA

Communicable diseases—May, 1926.—During the month of May, 1926, communicable diseases were reported in the Republic of Esthonia, as follows:

Disease	Cases	Disease	Cases
Diphtheria	23	Scarlet fever	121
Leprosy	2	Smallpox	1
Measles	987	Tuberculosis	172
Paratyphoid fever	2	Typhoid fever	27

Population, 1,107,059.

JAMAICA

Smallpox (reported as alastrim)—May 30–June 26, 1926.—During the four-week period ended June 26, 1926, 99 cases of smallpox (alastrim) were reported in the island of Jamaica exclusive of Kingston No cases of alastrim were reported at Kingston.

Other diseases—Prevalence of other diseases was reported as follows: *Measles*—general, four cases; Kingston, 23 cases; *tuberculosis*, pulmonary, general, 44 cases; Kingston, 10 cases; *typhoid fever*, general, 43 cases; Kingston, 9 cases; *whooping cough*, general, 222 cases Population, estimated, 1921, 858,118, population of Kingston, 62,707.

MEXICO

Mortality—Communicable disease prevalence—Durango—June, 1926.—During the month of June, 1926, four deaths from tuberculosis, all forms, and four from typhoid fever were reported at Durango, Mexico Population, estimated, 35,000. Typhoid fever and paratyphoid were stated to be endemic. The prevailing diseases in the city and vicinity during the month of June, 1926, were stated to be dysentery, tuberculosis, typhoid fever, and whooping cough.

SALVADOR

Mortality—Communicable diseases—San Salvador—April, 1926.—During the month of April, 1926, 53 deaths from all causes, were reported at San Salvador, Republic of Salvador, including gastroenteritis 23 deaths, measles 6, tuberculosis 23, and typhoid fever 1 death. Population, 83,000.

Republic of Salvador—Mortality—Malaria.—During April, 1926, 2,710 deaths from all causes were reported in the Republic of Salvador. Population, 1,500,000 Malarial and related fevers were stated to be the prevailing diseases in the country.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarly for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 41 JULY 30, 1926 NO. 31

THE NATIONAL HEALTH SERVICE OF CHILE

A Brief Synopsis of the Achievements of the Service During the Year Ended July 1, 1926

By JOHN D LONG, Technical Adviser, Ministry of Hygiene, Chile, Surgeon, United States Public Health Service

In accordance with a decree law dictated by the first "Junta de Gobierno" (Decree Law No 44), the Chilean National Health Service has been completely reorganized The following synopsis of achievements during the past year will give a general conception of the present status of the health service and a glimpse into its future possibilities:

1 Constitutional guaranties (art 10, pars 10 and 14, Chilean constitution)

2 The National Sanitary Code, approved October 13, 1925, which includes the ratification of the Pan American Sanitary Code (an international sanitary treaty) and a chapter on foods and drugs.

3. Frontier and maritime quarantine regulations

4. Regulations for the control of the importation and sale of opium, cocaine, and their derivatives.

5 Regulations relative to the practice of medicine and the other healing arts.

6 Regulations relative to the control of prostitution.

7. Regulations for the administration of the headquarters office of the health service

8. Graphic chart of the health service organization.

9 Graphic chart of the functions and duties of the officials and employees.

10 Physical examination blank and regulations relative to the periodic physical examination of all school children.

11. Regulations relative to sewage disposal in small towns, villages, and small districts

12. Regulations relative to pharmacies and drug stores

13. A model municipal sanitary code to be utilized by cities, towns, and villages in the preparation and drafting of sanitary ordinances and regulations.

14. A school for the instruction of visiting public health nurses, and a course of instruction for sanitary inspectors.

15. A model sanitary latrine, for use in small towns and rural districts where public sewer systems do not exist, for the prevention of the contamination of the soil, of surface waters, and of wells that supply water for domestic use.

16. There has been devised and plans are now being prepared for a sanitary type of house or home which can be quickly constructed of native materials at a relatively small cost.

17 A sanitary type of well has been devised for supplying reasonably safe water for domestic use in small towns or rural districts where public water supplies are not available

18 Numerous public addresses on public health have been delivered in a number of different cities. Intense interest has been manifested on all occasions

19. Public interest in improving sanitary conditions and in reducing morbidity and mortality has been apparently thoroughly aroused, as evidenced by letters received and numerous personal visists and interviews, as well as by sanitary improvements that are being voluntarily made

20 Fly extermination campaigns have been carried on with quite appreciable reductions in death rates, especially in the infant mortality.

21 Eleven boards of health have been organized in an equal number of cities and are now functioning

22 Ten sanitary zones, comprising the entire Republic, have been formed

23. The sanitary zones have been subdivided into 83 sanitary divisions; a considerable number are now functioning and the remainder will be soon.

24. Officials and employees have been physically examined and placed in the new organization or recommended for retirement, in accordance with the circumstances in each case

25. Appointments have all been approved by the President and the Minister of Hygiene, but not by the Minister of the Treasury, except in a few instances.

26 Officials and employees have been assigned, and the majority have gone, to their various posts or stations and are actually functioning.

27 The appropriation law for 1926, has been drafted and presented to the Minister of Hygiene

28. The principal points to be considered in the appropriation law for 1927, have been indicated.

29. A study of the principal sanitary problems of the country has been made, and their solutions have been indicated.

30. Widespread public interest has been aroused in the improvement of public water supplies, and a number of cities are insisting upon improvements in existing supplies.

From the above it may be seen that Chile now has a complete modern health organization based upon national and international needs and obligations.

With sufficient funds, reasonable freedom of action, full time health officials, and a reasonable amount of study of problems and application of the measures indicated, results should be equal to those obtained in other countries, some of them not so favorably situated as Chile, that have applied the same principles with entirely satisfactory results in the reduction of morbidity and mortality and the prolongation of the average expectancy of life.

REPORT OF THE COMMITTEE ON UNIFORM STANDARD MILK ORDINANCE, CONFERENCE OF STATE AND TERRITORIAL HEALTH OFFICERS, 1926

Your committee, appointed by resolution of the 1925 Conference of State and Territorial Health Officers, was instructed "To make a careful study of the milk ordinance which has been adopted as standard by eight States, and to submit a report to the 1926 conference as to whether this ordinance or any modification thereof is suitable for general adoption by the State health officers of the United States"

In presenting its report your committee believes that attention should first be given to the theoretical considerations underlying the need for a standard milk ordinance, and the general principles upon which its construction should be based.

It wishes to include as an appendix to its report, therefore, a paper by Sanitary Engineer Leslie C. Frank, of the United States Public Health Service, which discusses these questions thoroughly.[1]

Your committee is in accord with the general conclusions reached in that paper, namely—

(1) That a uniform standard ordinance is vitally necessary in order to increase the general level of milk quality and safety in the United States, in order to elicit the cooperation of the dairy industry, and in order to promote a greater milk consumption.

(2) That proper criteria for an effective standard milk ordinance are—

(a) It must be designed to effect the maximum percentage of pasteurization which each city will support.

(b) It must improve as rapidly and as much as possible the quality of the milk before pasteurization.

(c) It must improve as rapidly and as much as possible the quality of any portion of the milk which remains unpasteurized.

(d) It must encourage greater milk consumption.

(e) It must elicit the cooperation of the dairy industry.

(f) It must be so framed as to be likely to be enacted by both small and large cities; cities with little or no previous milk control, and cities with long experience in milk control; cities with a majority sentiment in favor of pasteurization, and cities with a majority sentiment opposed to pasteurization.

(g) It must therefore be so designed as not to exclude the many cities which can not be induced to enact a universal pasteurization ordinance and the many cities which can not be induced to enact an ordinance which limits the sale of milk to the highest ideal grade.

[1] A National Program for the Unification of Milk Control, p 1583, of this issue

(3) That in order to satisfy all of these conditions the ordinance must be of the multiple grading type, providing a number of grades of both raw and pasteurized milk.

(4) That the grades of milk to be provided for in the Standard Milk Ordinance should be—

(a) *Grade "A" pasteurized milk.*—This grade should be milk which has been produced in a cleanly manner and under all major safety precautions, and which has been properly pasteurized in a properly designed and properly operated plant.

(b) *Grade "B" pasteurized milk*—This grade of milk should be milk in the production of which certain items, such as tuberculin testing of cows or health examination of employees, may not have been applied, but which has been produced in a cleanly manner, and which has been properly pasteurized in a plant in which only minor items of sanitation may have been found to be violated.

(c) *Grade "C" pasteurized milk.*—This grade should comprise all pasteurized milk not complying with either grade "A" or grade "B" pasteurized requirements.

(d) *Grade "A" raw milk.*—This grade of raw milk should be the highest which it is practicable to produce. It should meet certain production refinements, such as a very low bacterial count, a very low cooling temperature, and certain structural details which most authorities believe can not be practicably required of grade "A" pasteurized milk.

(e) Finally, the grades of raw milk used for each of the three grades of pasteurized milk should be defined in the ordinance.

(5) That any grade of raw milk, however carefully produced, is made still safer by pasteurization.

(6) That the highest grade of pasteurized milk should place ample emphasis upon proper production methods as well as proper pasteurization methods.

(7) That each city should be encouraged to require the maximum percentage of pasteurization which its citizens will support.

(8) That cities which feel that all of their milk supplies can be required to comply with all of the items of sanitation for the highest grade of milk defined in the ordinance, namely, grade "A" pasteurized, may limit the sale of milk to that one grade.

(9) That cities which feel they can not require all of their milk supplies to equal grade 'A' quality should be permitted to sanction the sale of the other grades defined in the ordinance, but should be urged to inform their citizens that grade 'A' pasteurized milk is the safest milk, by placards in all restaurants, soda fountains, etc., where milk is sold, and by other means.

Your committee believes that the Standard Milk Ordinance tentatively proposed by the United States Public Health Service [2] and now adopted as standard by 10 States, admirably satisfies in general the above requirements.

Believing that the States which are actually applying this ordinance should be well qualified to render judgment as to the effect of its application, your committee has made inquiries of each of these States concerning the effect of the operation of the ordinance.

The three States which feel they have been applying the Public Health Service Standard Milk Ordinance long enough to justify conclusions are North Carolina, Texas, and Alabama

North Carolina and Alabama have now been applying this ordinance for about three years, and Texas has been applying it for about two and one-half years In these three States over 60 cities are now operating under the ordinance Each of the States reports to your committee that its experience with the operation of the ordinance is satisfactory, and none of them suggests modification, except that Texas suggests that it would like it to be made more adaptable to its "smaller communities which are without laboratories and from which it will not always be practicable to ship samples of milk to central laboratories."

The State which has been operating longest under the Standard Milk Ordinance is Alabama, and that State reports that following the application of the Standard Ordinance in eight of its cities the results described below have been noted.

(1) The enforcement of the Public Health Service Standard Milk Ordinance has been followed by a greatly improved milk sanitation

Table 1 shows the increase in the general milk sanitation ratings (on the basis of the Public Health Service rating plan) of eight Alabama cities which have now been operating under the Standard Milk Ordinance long enough to make it possible to measure results.

TABLE 1.—*United States Public Health Service milk sanitation ratings (general)*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Rating	Date	Rating	
Montgomery	January, 1923	35 6	December, 1925	59 1	66 0
Florence	March, 1924	24 5	do	48.8	99 2
Selma	do	29 1	do	47 8	64 3
Tuscaloosa	do	29 7	do	62 7	111 1
Mobile	September, 1923	27 1	do	48 2	77 8
Huntsville	March 1924	27 0	do	67 1	148 5
Gadsden	January 1924	28 5	do	47 1	65 3
Albany-Decatur	March, 1925	8 1	do	73 3	805 0
Averages (weighted) [a]		29 2		54 2	85.6

[a] Weighted on gallonage consumption basis

[2] A State-wide Milk Sanitation Program (Appendix A) By Leslie C Frank Pub Health Rep, vol 39, No 45 Nov 7 1924 (Reprint No 971)

The above figures show that there has been in these eight cities an average increase of well over 80 per cent in milk sanitation since the passage of the milk ordinance. It would be unwarranted, of course, to state that no other milk ordinance would have accomplished the same improvement in the same length of time, but it is believed conservative to state that the present ordinance does effect a significant increase in milk sanitation if properly enforced

In order to bring out the relative improvement in production and pasteurization ratings, Tables 2 and 3 are given below.

TABLE 2.—*United States Public Health Service milk sanitation ratings (production)*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Rating	Date	Rating	
Montgomery	January, 1923	67 2	December, 1925	93 9	39 7
Florence	March, 1924	49.0	do	97 5	99 0
Selma	do	58 2	do	95 5	64.0
Tuscaloosa	do	53.3	do	94.0	76.4
Mobile	September, 1923	54 2	do	96 4	77.8
Huntsville	March, 1924	54.0	do	95 2	76.3
Gadsden	January, 1924	57 0	do	94 3	65 4
Albany-Decatur	March, 1925	16.2	do	80 8	398 5
Averages (weighted) [1]		56.8		94 8	66 9

[1] Weighted on gallonage consumption basis

Table 2 shows that the average production improvement in the eight cities has been 66.9 per cent, and that the individual production ratings for all except one of the eight cities are now well over 90 per cent, signifying that production sanitation has in these eight cities been brought to a high level within a comparatively short period of time.

TABLE 3.—*United States Public Health Service milk sanitation ratings (pasteurization)*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Rating	Date	Rating	
Montgomery	January, 1923	4 0	December, 1925	24.4	510 0
Florence	March, 1924	0	do	0	0
Selma	do	.0	do	0	0
Tuscaloosa	do	6.2	do	31 3	405 0
Mobile	September, 1923	0	do	0	0
Huntsville	March, 1924	.0	do	38 9	
Gadsden	January, 1924	.0	do	.0	.0
Albany-Decatur	March, 1925	.0	do	65.8	
Averages (weighted) [1]		1 6		13 5	744.0

[1] Weighted on gallonage consumption basis

Table 3 shows that for the eight cities as a whole the pasteurization ratings were practically zero when the work began, that the percentage increase in the pasteurization ratings of four of the eight cities has

been large, but that the other four of the eight cities are still without pasteurization facilities.

The operation of a pasteurization plant in one of these cities, Florence, to pasteurize all of the city's milk supply, was begun on April 15, 1926. This city's pasteurization rating, therefore, advanced to nearly 100 per cent following the establishment of the plant.

In the other three cities sentiment is still strongly against pasteurization, but it is believed that opinion will lean more and more toward pasteurization as the educational work continues. In the meantime the consumers are being protected as much as possible by high production precautions.

(2) *The enforcement of the Public Health Service Standard Milk Ordinance has been followed by an increase in the volume of market milk sales*

Table 4 shows the increase in the volume and percentage of market milk sales in the eight Alabama cities previously considered.

TABLE 4 —*Increase in market milk consumption*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Gallons per day	Date	Gallons per day	
Montgomery	January, 1923	1,588	December, 1925	2,713	70.9
Florence	March, 1924	277	March, 1925	345	24 5
Selma	do	605	do	669	10 6
Tuscaloosa	do	505	April, 1925	687	36 0
Mobile	September, 1923	[1] 2,000	December, 1925	3,351	67 6
Huntsville	March, 1924	365	March, 1925	417	15 3
Gadsden	January, 1924	362	December, 1925	370	2.2
Albany-Decatur	March, 1925	177	do	220	24 3
Totals and average		5,879		8,772	49 2

[1] Estimated

The average increase in market milk sales, following the application of the Standard Milk Ordinance, can not be interpreted to indicate the true increase in total milk consumption, as we are dealing with small cities in which the number of family cows is high and in which a fairly large percentage of the total milk consumed is from private cows. Again, it would not be scientifically sound to conclude that the increase in the consumption of milk has been caused by the application of the Standard Ordinance itself. However, the figures do indicate the actual increase in *market milk consumption*, and it is believed that while it is conceivable that some other cause could have been operative, this is not deemed likely.

Your committee wishes further to report that the Standard Milk Ordinance has, in general, elicited the support of the dairy industry. In a large number of the cities now operating under the Standard

Ordinance the passage of the ordinance was urged by the dairy industry itself

The support of the dairy industry is further illustrated by the indorsement given the Public Health Service program by the National Dairy Council, a national organization of the dairy interests.

Finally, the support of the dairy industry is evidenced by the fact that, so far as known, only two or three court cases have occurred in connection with milk control in all of the many cities now operating under the ordinance. None of these court cases has been decided against the city.

Your committee wishes further to report that the Public Health Service Standard Milk Ordinance has been enacted by practically all types of cities.

In the 10 States which have thus far adopted the Standard Milk Ordinance, the many cities which have enacted the ordinance into law include the largest cities in those States, cities with as small a population as 5,000, cities which had previously done no milk-control work whatever, cities which have spent many years in improving milk supplies, cities which are willing to require 100 per cent pasteurization, and cities which are largely opposed to pasteurization.

Your committee believes, therefore, that it may safely be stated that the ordinance is so framed as to be attractive to the majority of types of cities. However, it should be noted that none of the States in which the ordinance has become standard has cities of over 500,000 population, and it still remains for actual future experience to demonstrate whether the ordinance will be attractive or can be modified so as to become attractive to such large cities. On the other hand, your committee wishes to suggest in this connection that the principal problem with which we as State health officers have to deal is not that of our largest cities, as these in general have done far better milk sanitation work than the average in the State as a whole, but that our principal problem is rather that of our many smaller cities which are in general not yet advanced in milk-control methods.

PROPOSED MODIFICATIONS OF THE ORDINANCE

The Public Health Service has taken the position that its principal object is not to insist upon the exact wording of its present Standard Milk Ordinance, but rather to emphasize the vital need for the uniform adoption by the State health officers of the United States of the ordinance as it now stands or of any modification of the ordinance which is theoretically sound and practically effective.

Your committee has therefore been open to proposed modifications which might lead to general agreement and wide application.

The following modifications have thus far been suggested to your committee:

Proposed modification No. 1.—Section 1, definition: Add a definition for chocolate milk as follows. "Chocolate milk is defined as whole or adjusted or skim milk to which has been added in a sanitary manner a chocolate sirup composed of wholesome ingredients, and which is labeled with the grade of milk or milk products from which it is made. If chocolate milk contains less than 3¼ per cent milk fat the label shall indicate the percentage of milk fat to which the milk has been adjusted." It is recommended that this section be made optional with States.

Proposed modification No 2—Section 1, definition, adulterated milk and milk products· Change this definition to the following. "Any substance claimed to be any milk or milk product defined in this ordinance but not conforming with its definition as given in this ordinance shall be deemed adulterated and misbranded"

Proposed modification No. 3—Section 1, definition C. Change the minimum milk fat percentage for light creams from "18 per cent" to "18 per cent, preferably 20 per cent." Insert "containing not less than 30 per cent milk fat" after "whipping cream and manufacturing cream are creams"

Proposed modification No 3–a.—Delete definition E.

Proposed modification No 4—Section 1, definition O Insert "every particle of" after "shall be taken to refer to the process of heating" Change the pasteurization temperature from 142° to 145°

Proposed modification No 4–a—Definitions Q and S· Add the following sentence to each of these. "This section shall not be construed to include what is generally known as 'family cows.'"

Proposed modification No 5—Section 1, definition V Insert 'of the" after "to mean the average." Change "count" to "counts"

Proposed modification No 6—Section 4 Delete "(5) The percentage of milk fat if the package or other container encloses adjusted milk" and substitute therefor. "(5) Name of producer or distributor"

Add at the end of the first paragraph the following. "The label or mark shall be in letters of a size and kind approved by the health officer and shall contain no marks or words not approved by the health officer"

Insert "at all times" after "every grocery store, restaurant, * * * shall display."

Change the period at the end of section 4 to a comma, and add the following: "and including the following statement· 'The Safest Grade of Milk is Grade 'A' Pasteurized.'"

Proposed modification No. 6–a.—Section 5· Add at end of first paragraph: "Two violations of this ordinance within any one grading period shall call for immediate de-grading."

Proposed modification No. 6–b.—Section 6: Add "plate count method of" after "conformity with the" in third sentence of first paragraph.

Proposed modification No. 7.—Section 7. Delete "daily" in first sentence. Insert "and of the State Board of Health or City or County Health Officer" after "Medical Society of ——— County."

Proposed modification No. 8—Section 7, first paragraph· Delete "except that the permissible bacterial limits shall be multiplied fivefold in each case"

Proposed modification No 9—Grade "A" raw milk, cows, tuberculosis and other diseases. It is proposed that this item of sanitation be made identical with the new official wording approved by the Bureau of Animal Industry, provided that this wording shall be made to include isolation of infected animals and proper requirements concerning the addition of new cows to the dairy herd.

Proposed modification No 10.—Grade "A" raw milk, item 2: Change to "Such sections of all dairy barns where cows are kept or milked shall have at least three square feet of window space for each stanchion."

Proposed modification No 11—Grade "A" raw milk, item 3 Change to "Such sections of all dairy barns where cows are kept or milked shall have at least five hundred (500) cubic feet of air space per stanchion, and shall be well ventilated."

Proposed modification No 12—Grade "A" raw milk, item 4. Change the first part of the first sentence so as to read. "The floors and gutters of such parts of all dairy barns in which cows are kept or milked shall be constructed of concrete or other equally impervious * * *" Add at end of item "No horses, pigs, fowl, etc , shall be permitted in parts of the barn used for dairy purposes "

Proposed modification No 13—Grade "A" raw milk, item 5 Change the last sentence to read as follows "In case there is a second story above that part of the barn in which cows are kept or milked, the ceiling shall be tight "

Proposed modification No 14—Grade "A" raw milk, item 8 Change "cement" to "concrete" Add "and ventilated" after "the milk house shall be well lighted " Add "and the washing and sterilizing of milk apparatus and utensils" before the comma after the words "Storage of milk" in the first sentence

Proposed modification No. 15—Grade "A" raw milk, item 12 Insert "non-absorbent material and of" after "all containers or utensils used in the handling or storage of milk or milk products must be of "

Proposed modification No 16—Grade "A" raw milk, item 13 Change this item to read "All containers and other utensils used in the handling, storing, or transportation of milk and milk products must be thoroughly cleaned after each usage "

Proposed modification No 17.—Grade "A" raw milk, item 14. Change to read. "All containers and other utensils used in the handling, storage, or transportation of milk or milk products shall between each usage be sterilized with steam or chlorine or in a manner approved by the State health authority "

Proposed modification No. 18—Grade "A" raw milk, item 17: Change this item to read as follows: "The udders and teats of all milking cows shall be clean at the time of milking "

Proposed modification No 19—Grade "A" raw milk, item 19. Add at the end of this paragraph "Convenient facilities shall be provided for the washing of milkers' hands " Item 20· Add "and milk handlers" after "milkers " Item 22. Add "or straining room" at the end of the first sentence

Proposed modification No. 20—Grade "A" raw milk, item 24 Delete "preferbly" in first sentence. Change last sentence to read "Caps shall be purchased in sanitary tubes and kept therein in a clean place until used."

Proposed modification No 21—Grade "A" raw milk, item 25· Change this item to read as follows· "Every person connected with a dairy or milk plant whose work brings him in contact with the production, handling, storage, or transportation of milk or milk products shall have within twelve months passed a medical examination made by the health officer "

Proposed modification No 22.—Grade "A" raw milk, item 26: Change "within twenty-four hours" to "immediately "

Proposed modification No. 23—Grade "B" raw milk Add after "which at no time prior to delivery exceeds 200,000 per cubic centimeter" the following: "or which falls in class 1 as determined by the reductase test as described in the Standard Methods of Milk Analysis of the American Public Health Association." Delete the following· "Item (14) shall apply except that boiling water may be substituted for steam."

Proposed modification No 24.—Grade "C" raw milk: After "which at no time prior to delivery exceeds 1,000,000 per cubic centimeter," add the following: "or which falls in class 2 as determined by the reductase test as described in the Standard Methods of Milk Analysis of the American Public Health Association."

Proposed modification No. 25.—Grade "D" raw milk: After "does not exceed 5,000,000 per cubic centimeter" add the following: "or which falls in class 3 as determined by the reductase test as described in the Standard Methods of Milk Analysis of the American Public Health Association"

Proposed modification No 26—Grade "A" pasteurized milk, item 1. Insert "constructed of concrete or other equally impervious and easily cleaned material and shall be" after "floors of all rooms in which milk is handled shall be" Delete "impervious" from the original reading occurring after the word "smooth."

Proposed modification No 27.—Grade "A" pasteurized milk, item 5 Insert after first sentence the following "This requirement shall be interpreted to include separate rooms for (*a*) the pasteurizing, cooling, and bottling operations, (*b*) the container-washing and sterilizing operation. Cans of raw milk shall not be unloaded directly into the pasteurizing room"

Proposed modification No 28—Grade "A" pasteurized milk, item 6. Add at the end of second sentence "or stored"

Proposed modification No 29.—Grade "A" pasteurized milk, item 8: Change "wash room" to "washing facilities", change "equipped with" to "including"

Proposed modification No 30.—Grade "A" pasteurized milk, item 12. Change the wording of this item to the following "All milk containers and milk apparatus shall be thoroughly cleaned after each usage and sterilized in a manner approved by the health officer immediately before each usage"

Proposed modification No 31—Grade "A" pasteurized milk, item 13. Change "in an inverted position and in a clean place" to "in such manner as to be."

Proposed modification No. 32.—Grade "A" pasteurized milk, item 16. Add "dated and" after "the time and temperature record charts shall be."

Proposed modification No. 33—Grade "A" pasteurized milk, item 17: Change "upon receipt shall be" to "within two hours after it is received at the plant shall then be."

Proposed modification No 34—Grade "A" pasteurized milk, item 18: Add after "bottling shall be done" the following: "in automatic machinery approved by the health officer"

Proposed modification No 35.—Grade "A" pasteurized milk, item 22: Change the wording of this item to read as follows: "Every person connected with a dairy or milk plant whose work brings him or her in contact with the production, handling, storage, or transportation of milk or milk products shall have within twelve months passed a medical examination made by the health officer."

Proposed modification No 36.—Grade "A" pasteurized milk, item 23: Change "within twenty-four hours" to "immediately."

Proposed modification No. 37—Grade "C" pasteurized milk: Delete the last sentence beginning "Grade 'C' pasteurized milk shall be sold for cooking and manufacturing purposes only," etc

Proposed modification No. 38—Section 17, proscribed milk: It is suggested that this item be changed to read as follows: "Milk which does not conform with the following grades as described in this ordinance shall not be sold in the city of ——— —————————." (Any city which wishes to prohibit the sale of any of the grades of milk described in this ordinance may use this section for that purpose.)

Proposed modification No 39—Section 13, vehicles: Add "in such manner as to permit contamination."

Proposed modification No 40—Section 16: Add "which shall not be less than the Grade A requirements of this ordinance."

Your committee has made a careful study of each one of the above suggested modifications. It does not believe that any of them, with two or three exceptions, will either detrimentally affect the operation

of the Standard Ordinance or lead to disagreement. In fact, it believes that the proposed modifications will, if adopted, encourage a wider usage of the ordinance

The several proposed modifications which your committee feels may lead to disagreement are as follows

Proposed modification No 4, second part "Change the pasteurization temperature from 142° Fahrenheit to 145° Fahrenheit" Health officials seem to be about equally divided in their support of the two temperatures Your committee believes, however, that pending the outcome of future research work the temperature required by the ordinance should be 145° F, because this temperature gives the public the benefit of all doubt from a public health standpoint

Proposed modification No 17 This modification has been suggested by a State health department which believes that chlorine sterilization should be accepted as being as effective as steam sterilization It is believed that a number of health officers will disagree with this as not having been proved, particularly in view of the doubtful results which have been secured in the sterilization of milking machines by means of chlorine Your committee feels, however, that inasmuch as this is a debatable point, it will be wise to include the modification and invite such health officials as prefer to require steam expressly to do so.

Proposed modifications Nos 23, 24, and 25 These modifications propose the alternative acceptance of the reductase test in place of the bacterial count The proponents of the modification hold that the requirement of the bacterial count will be too costly for large cities with milk sheds of long radius, and that the accuracy of the bacterial count has been much overrated. The opponents to the modification hold that the reductase test is too crude.

Here, again, your committee feels that we are dealing with a debatable issue. Therefore it recommends that the proposed modification be included in the Standard Ordinance and that such States and cities as oppose it eliminate it as a local adaptation of the ordinance.

Your committee wishes to point out, in connection with the above recommended action, that any city which adopts the ordinance as above outlined will not have violated the spirit of the Standard Ordinance, which is that of "*minimum requirements*."

In conclusion, your committee has the honor to recommend that the Standard Milk Ordinance of the United States Public Health Service, modified as above suggested, be adopted by this conference as a uniform standard for the United States, with the understanding that small communities without laboratory facilities may pass the ordinance with the laboratory requirements deleted, and be recognized as having adopted the "Junior Standard Ordinance."

The members of the committee on uniform standard milk ordinance:

E. L. BISHOP,
Members.

A NATIONAL PROGRAM FOR THE UNIFICATION OF MILK CONTROL[1]

By LESLIE C. FRANK, Sanitary Engineer, United States Public Health Service

During the past three years the United States Public Health Service has been encouraging the adoption of a uniform, effective milk sanitation program by the cities and States of the United States. On May 25, 1926, the Standard Milk Ordinance of the United States Public Health Service, slightly modified, was adopted as a standard for the United States by the Conference of State and Territorial Health Officers. The purpose of this paper is to discuss the conditions which make such a program advisable, to describe the program itself, and to discuss the progress made thus far.

A uniform effective milk control program is advisable because our present chaotic state of milk control in the Nation as a whole is permitting the occurrence of many milk-borne outbreaks of communicable disease

Trask[2] listed 500 outbreaks of milk-borne communicable disease as having been reported in the literature during the 27-year period, 1880 to 1907. The numbers of outbreaks reported for the various diseases are given in Table 1.

TABLE 1.—*Milk-borne disease outbreaks, 1880–1907 (Reported in United States and foreign countries)*

Disease.	Number of outbreaks
Typhoid fever	317
Scarlet fever	125
Diphtheria	51
Septic sore throat and pseudodiphtheria	7
Total number of outbreaks	500
Total number of outbreaks reported in the United States	168
Total number of outbreaks per year in the United States	6

In 1924 the Office of Milk Investigations of the United States Public Health Service made a questionnaire survey of milk-borne outbreaks occurring in the registration cities of the United States during the six-year period 1918 to 1923, inclusive. Table 2 gives the number of outbreaks reported.

TABLE 2.—*Milk-borne disease outbreaks in registration cities of the United States, 1918–1923, inclusive*

Disease:	Number of outbreaks
Typhoid fever	87
Scarlet fever	16
Diphtheria	4
Septic sore throat	4
Dysentery	1
Total number of outbreaks	112
Total number of outbreaks per year	18 7

[1] Expanded from a paper read at the American Health Congress, Atlantic City, N J, May 20, 1926

[2] United States Public Health Service Bulletin No 56

It will be noted that the rate of milk-borne outbreaks per year in the United States reported for the period 1918 to 1923 is 18.7, whereas the rate shown by the literature survey for 1880 to 1907 was 6. This does not necessarily mean that there has been an increase in the milk-borne outbreak rate, but rather that a questionnaire survey tends to give more complete returns than does a literature survey. Many epidemics not reported in the literature will be disclosed by a questionnaire.

In 1925 a questionnaire survey was made of milk-borne outbreaks occurring in 1924, with the following results:

TABLE 3.—*Milk-borne disease outbreaks reported in the United States during 1924*

Disease:	Number of outbreaks
Typhoid and paratyphoid fever	35
Scarlet fever	5
Diphtheria	1
Septic sore throat	1
Dysentery	2
Total number of outbreaks in 1924	44

A rate of 44 outbreaks per year for 1924, as shown in Table 3, is large compared with the rate of 18.7 outbreaks per year for the period 1918 to 1923. Here again, however, it is improbable that there was an actual increase in the milk-borne outbreak rate. It is more likely that the apparent increase indicates that the health office records of 1924 are more nearly complete than the records for the period 1918 to 1923, or that the health authorities are more active in identifying these outbreaks. City health officers come and go in many cities with distressing frequency, and records are often submerged in the transfer of the office.

However, the number of milk-borne outbreaks of disease is far greater than has hitherto been assumed; and it is evident that our past milk-control efforts, nationally considered, have not been adequate. There has been no effective leadership, no respected and uniform national program; hence health officers, bewildered by the array of milk ordinances from which to choose, have often chosen ineffective ones.

This constitutes the first reason why a uniform and effective milk-control program is advisable.

A uniform milk-control program is advisable because our present non-uniform methods have caused the dairy industry to discredit the health officer's knowledge of milk sanitation

There can be no doubt that there is at present in the United States little evidence of unity of thought among health officers in matters of milk control. Until very recently there have been almost as many different ordinances as there were health officers to write them.

We can, therefore, hardly criticize the dairy industry in general for doubting the soundness of the average health officer's knowledge of milk control. It can readily be understood that the dairyman has come to feel that "among so many different practices, some must be wrong. They can not all be sound." In fact, in many localities the dairyman has come to feel that the local milk ordinance is the personal invention of an individual untrained in the particular branch of public health involved, and is partly composed of requirements which have no real public health significance and which are unnecessary economic burdens upon the dairymen.

It is easy to understand, therefore, that many members of the dairy industry have developed a spirit of resistance to milk ordinances in general. A dairyman who doubts the health officer's knowledge of milk control will not carry out willingly an ordinance devised by that health officer This lack of respect for the health officer's knowledge by many persons in the dairy industry is believed to be partly responsible for the fact that the local milk ordinance is so unsatisfactorily complied with in so many communities

This is the second reason why it is advisable to establish a uniform and effective milk-control program in the United States We must earn the respect of the dairy industry before we can expect to achieve the optimum results in milk control.

A uniform and effective milk-control program is necessary because our present conflicting methods of milk control are partly responsible for a lower milk consumption than is desirable from a public health point of view

Many intelligent milk consumers seek advice of the pediatrician when they wish to secure a safe milk for infant feeding, and the pediatrician seldom gives *carte blanche* approval of the general market milk supply. He usually advises the purchase of "certified" milk, or the milk of some special dairyman This can only mean that the consumer and the pediatrician distrust the general milk supply. The very existence of medical milk commissions for the control of "certified" milk is, in effect, evidence that the consumer has found it advisable to set up a special unofficial health organization for the purpose of providing a safer milk supply than the health officer has provided.

It follows naturally as a result of this attitude on the part of the pediatrician that the consumer should begin to ask himself this question: If the general market milk supply is not safe enough for consumption by my baby, is it safe enough for consumption by the others of my family? And so we have a force working in the direction of low milk consumption, the opposite of which should be desired by every thoughtful health official. This general distrust of milk

quality on the part of the consumer is strengthened by the frequent exhibitions of resistance to the local milk ordinance displayed by the dairy industry, and is further strengthened by the frequent campaigns on the part of the local health officer for a new milk ordinance.

Under the present system of a confusion of local milk ordinances, many incoming health officers inaugurate campaigns for a new milk ordinance. The old milk ordinance, written by the previous health officer, is condemned and the milk-consuming public is advised that the dangers of the present milk supply are such as to make it necessary to pass an entirely new milk ordinance To the consumer this means a frequent confession on the part of the official health agency that the general city milk supply is not as safe as it might be Can we wonder, then, that the consumer drinks on the average about three quarters of a pint per day instead of the quart per day recommended by specialists?

It must be evident to the thoughtful person that a program of unification and stabilization of milk-control methods is necessary. It is difficult to conceive of a more unfortunate condition than the present one in which many producers of milk and many consumers of milk fail to have the proper confidence in the controlling official.

A uniform national milk control program is desirable because we are rapidly entering the era of interstate milk shipments, the successful control of which must inevitably be based upon uniform State standards if Federal control is to be avoided

During the early period of milk-control history, practically all communities received their milk supplies from immediately surrounding areas. This made a relatively short radius problem of milk control. As our solution of the fluid milk transportation problem has developed, however, it has become correspondingly easier for areas producing milk in large quantities to supply the demands of areas producing in small quantities, even where great distances intervene. For example, Florida is now receiving milk shipments from northern States. We are dealing here with an economic force which will unceasingly strive to establish a uniform milk-price level, and this can be done only by the removal of barriers to the free interstate shipment of milk. If, now, our control of these ever-increasing interstate milk shipments is to be logical and effective, it must be based eventually upon uniform interstate standards. To-day the State health officer of Florida is asking the State health officer of Alabama, "What is the quality of the milk which Alabama is shipping into Florida?" We need here a universal milk-control language. Compliance with Alabama standards may not satisfy Florida, and Alabama will not be willing to apply a different standard for every different State to which it may ship milk. This is, then, the fourth reason why a uniform national milk-control program is advisable.

Within recent years certain States have realized the need for a uniform milk-control program

During the past 10 years a few States have come to realize that State leadership is needed in order to achieve a unified milk-control program Thus, certain States have adopted various types of State milk ordinances, which they have then recommended for enactment by their various cities This has resulted in some good locally in improving milk supplies

It is even more necessary, however, to unify State standard ordinances than it is to unify the municipal milk ordinances within the State

It must be obvious that, unless the States now agree upon one uniform ordinance, we shall merely have advanced from a condition of intrastate to a condition of interstate confusion Now is a good time, when, for all practical purposes, the adoption of State standards is just beginning to advance from the idea of individual State ordinances to its logical and inevitable final conclusion, namely, a National standard

Ten States have within the past three years subscribed to the standard ordinance of the public health service

Although prior to 1923 no two States were operating under the same State milk ordinance, since 1923 ten States have, in rapid succession, adopted as standard an ordinance recommended by the United States Public Health Service. In these States nearly [illegible] communities have enacted the ordinance into law. The first State to adopt the Public Health Service program was Alabama, followed by North Carolina, Texas, Virginia, Tennessee, South Carolina, Missouri, Kentucky, Arkansas, and Louisiana, in the order named. There seems, therefore, to be some basis for the hope that within a reasonable period of time the majority of the States will be operating under one uniform milk-control program.

The Public Health Service Program for the unification of milk control involved four major items:

(1) The development of a practical standard milk ordinance.

(2) The encouragement of its adoption by States and its enactment by communities.

(3) The development of a policy of relationship between the cities, the States, and the Federal Government to promote effective enforcement of the ordinance.

(4) The development of a method of measuring the results of the enforcement of the ordinance.

The first part of the program was the development of a standard milk ordinance which would be generally applicable and generally effective in providing safe milk and stimulating its adequate consumption

In the endeavor to develop a standard ordinance it was decided first to set down the criteria to be used.

The following criteria were used in the development of the United States Public Health Service Standard Ordinance

(1) It must achieve the maximum practicable degree of milk safety

(2) It must encourage greater milk consumption

(3) It must elicit the cooperation of the dairy industry.

(4) It must be so framed as to be likely to be enacted by both small and large cities; cities with little or no previous milk control, and cities with long experience in milk control; cities with a majority sentiment in favor of pasteurization, and cities with a majority sentiment opposed to pasteurization.

Before applying the criteria in developing a standard ordinance it was necessary to know what was meant by safe milk

The easiest approach to the answer to the question, What is meant by safe milk? is believed to be through the answer to the question, Is the highest grade of raw milk which it is practicable to produce sufficiently safe? It would have simplified matters to have been able to answer this question affirmatively. There still remains considerable opposition to pasteurization, and most ordinances developed upon the principle that the highest grade raw milk is not sufficiently safe will meet with this opposition. After careful consideration a negative answer was found unavoidable. Experience in the operation of high-grade raw-milk dairies leads to the conviction that no precautions humanly possible are in practice sufficient to prevent at all times the transmission of disease organisms through raw milk.

Tuberculin testing is an important public-health measure. After years of consistent tuberculin testing, however, a small residual percentage of reactors will persist. Tuberculin testing should, therefore, be regarded by both the health officer and the industry as an important factor of safety from the public health point of view, and as an economic necessity for the dairy industry (it is simply bad business for the dairyman to permit tuberculosis to spread through his herd), *but not as a final and complete safeguard.*

Periodic search for typhoid carriers is an equally important public health measure. Health officers should not neglect to employ any practicable measure which will help to keep carriers of typhoid fever

from having to do with milk production or distribution. But even the recent advances in the laboratory technique for the recognition of typhoid carriers can not solve the problem of intermittency of discharge of the organisms by the carrier. A carrier may or may not be discharging the organisms of typhoid fever on the day on which the specimens of feces and urine are collected. If the result of the laboratory test is positive, the result is significant, but if the result is negative it means that the organism was not found in the specimen examined, not that the person examined is not a carrier. Hence, again, while the health officer must regard the search for typhoid carriers among milk handlers as one important factor of safety in milk control, he should not regard it as a final and complete safeguard against the spread of typhoid fever by carriers, it does not discover all carriers

Furthermore, what is to be done with the milker in the presymptom infective period, the period during which the infectiveness is often the greatest? There are no practicable precautions which can obviate this danger. In the case of certain infections spread through milk a milker can be in an infective condition for several hours or days before he has any symptoms whatever to warn him of his infection. Finally, even if there were no presymptom infective period we would still have to deal with the problem of the milk handler who persists in working for a time after the beginning of first symptoms and before a diagnosis has been made as to whether his condition is infective or not.

The above reasoning applies equally well to "certified" milk or to any other "highest grade" of raw milk. The fact that epidemics do not occur frequently among the users of certified milk is sometimes advanced as evidence that certified milk is sufficiently safe. Unhappily, this evidence is not convincing. The ratio of epidemics among users of certified supplies to epidemics among users of noncertified supplies reported to the United States Public Health Service in 1924 is 1:43, whereas the ratio of certified to noncertified dairies in the United States is considerably less than 1 43. Obviously the comparison of these ratios can not be taken to mean that certified milk is no safer than the general supply, but just as certainly it can not be taken to mean that certified milk is without danger.

The above is not intended as a criticism of the certified-milk movement which has provided an extremely valuable service during the past quarter century in emphasizing the need of better milk sanitation in general and higher quality production methods in particular; but this just appraisal of the certified-milk movement does not, unfortunately, invalidate the conclusion that any raw milk, however carefully safeguarded, is made still safer by the process of pasteurization.

Shall we abandon production precautions entirely, then, and rely solely upon pasteurization? This is what has been done in effect by

certain of our cities, particularly the larger cities. In many of these cities the control of production is little more than paper control; it is neither real nor effective Certainly, one inspection per year, or less, can not be accepted as control, and some of our cities inspect their sources of pasteurized milk even less often

It is believed that a policy which abandons production precautions and relies solely upon pasteurization is not sound. There can be no reasonable doubt that pasteurization, if properly applied, will prevent milk-borne infections. Pasteurization is in this respect certainly superior to raw milk precautions. But, on the other hand, the pasteurization process is not always properly applied It is designed and operated by human beings Many of the designs are not sound, occasional slips in operation are inevitable. Suppose we abandon production precautions entirely or largely, suppose many of the cows are not tuberculin tested and that a high percentage of tuberculosis exists in the herd (true for many of our large cities); suppose that we take no precautions against typhoid carries on the farm, etc.; if, then, a failure in the pasteurization process does occur, our last safeguard is down, and the consumer is left defenseless.

Furthermore, a very serious opposition to pasteurization comes from the feeling on the part of the consumer that pasteurization makes it possible for the dairy industry to deliver low-grade milk to the consumer with impunity. It is easy to understand why this should arouse the opposition of the consumer and discourage him in the consumption of milk He wishes not merely a safe product but also one which satisfies his desire for cleanliness and wholesomeness.

A policy, therefore, which ignores production precautions and relies solely upon pasteurization must be considered not only as unsound from the standpoint of safety but also as undesirable from the standpoint of adequate milk consumption. With due consideration of all factors involved, it is believed that "safe" milk should be defined as follows:

Safe milk is milk which has been both properly produced and properly Pasteurized.

Under such a definition "safe" milk has a factor of safety of 2--two barriers have been erected between the consumer and the various sources of infection: Production precautions constitute one factor of safety and pasteurization constitutes the other. Neither one is sufficient by itself. Both must go hand in hand. Under such a policy we are following what we have learned with respect to water supplies, namely, that the single factor of safety provided by a patrolled watershed or by filtration should be further reinforced by a second safeguard, namely, disinfection by chlorination or other means.

The most direct and obvious type of standard milk ordinance is a single grade ordinance which simply sets down the requirements for the ideal safe milk described above, and which bars all other milk from the market

The enforcement of such an ordinance in any city would mean that no milk could be sold except such as had satisfied every necessary production requirement and had been properly pasteurized. Such an ordinance would undoubtedly provide the maximum in safe milk and, by increasing the confidence of the consuming public in milk quality, would encourage greater milk consumption It would be the ideal standard ordinance if cities in general could be induced to pass it and to enforce it. It is practically certain, however, that very few cities are sufficiently advanced to enact such an ordinance or to enforce it properly Years of experience in the passage of milk ordinances bring the conviction that only the occasional city can be induced at the present time to pass an ordinance requiring universal pasteurization. In most cities the public is not sufficiently convinced as yet of the imperativeness of pasteurization to be willing to favor such an ordinance, and one mistake that we should by all means avoid is to proceed faster than public opinion will follow:

Furthermore, the practical objections to this type of ordinance as a universal standard do not confine themselves to the pasteurization phase. There are many cities which will not at the outset pass an ordinance which requires the utmost in production precautions for all milk. Here, again, we must be guided by actual experience and not be carried away with a theoretical ideal. Most cities still have to make their first earnest attack upon the milk-sanitation problem; it is yet new to them. If these cities are suddenly approached with a proposal to pass an ordinance requiring that all dairymen immediately satisfy high production requirements, many of them will refuse because of the opposition of the dairymen. The legislators will heed the plea of many of the dairymen that the ordinance will entail a prohibitive expense, force many of them out of business, disastrously reduce the available milk supply, and increase the price of milk to the consumer. This picture will be immediately familiar to anyone who has made it a business to encourage the passage of milk legislation.

There is no question that this ordinance would be the ideal type if it could be generally enacted and enforced; but if we were to permit our scientific convictions to overrule our practical judgment and attempt to promote a standard ordinance of this type we should simply be doing paper work. The result would not be the greatest good for the greatest number. Clearly this type of ordinance will not satisfy the criterion that the standard ordinance must be one which most cities can be induced to pass.

A second type of milk ordinance is one which still attempts to retain the single-grade feature but which attempts to overcome part of the practical difficulties previously described by reducing production requirements

By this second type of ordinance is meant the universal pasteurization ordinance which a very few of our cities have passed and which places little or no emphasis upon production requirements. This ordinance is unquestionably effective in reducing milk-borne outbreaks, but it is not suited for use as a general standard, for two reasons First, because it is a universal pasteurization ordinance, and, as previously indicated, few cities can be induced to pass such an ordinance, second, because of the previously discussed objections to any ordinance which ignores or minimizes production requirements.

A third general type of ordinance is one which frankly recognizes the practical objections to a single-grade ordinance and which divides market milk into classifications

Most of the cites of the United States operate under some variant of this general type of ordinance.

There are a number of different types of multiple classification ordinances. The first and most frequently used type is one which simply divides milk into two classifications, "raw" and "pasteurized," and describes the items of sanitation which must be satisfied by each of these two grades of milk.

This type of ordinance would possibly be satisfactory as a general standard if the requirements of the one pasteurized grade of milk could be made strict enough to satisfy the fundamental definition of "safe" milk, if the requirements of the one grade of raw milk included everything except pasteurization, and if the ordinance were then still lenient enough to insure passage by the majority of cities.

Unfortunately, it seems impossible to satisfy these opposing requirements in the same ordinance. In the attempt to use this type of ordinance the usual practice has been to state that milk which is produced from tuberculin-tested herds and which satisfies certain other production requirements may be sold raw and that all other milk must be pasteurized. This is unsatisfactory because of the lack of sufficient emphasis upon production requirements for the pasteurized milk. Furthermore, it leaves the consumer with the impression that the health officer is permitting high-grade milk to be sold raw, while all other milk, good and poor alike, may be dumped into the pasteurization apparatus and sold as the highest and only grade of pasteurized milk on the market. This leaves the consumer dissatisfied and leads, as previously described, to an incentive to a low milk consumption.

On the other hand, the very fact that lower grades of milk are permitted to be delivered to the pasteurization plants, while no distinction is drawn between the lower and the better grades, leads to a poor production incentive Even dairymen of high principles have little incentive to maintain their production precautions when they know that their milk is to be dumped into the same vat with that of their lax competitors, who nevertheless, often receive the same price This type of ordinance is one which has been adopted by some northern cities, the condition of the raw-milk supply of many of which is deplorable

If now we attempt to remedy these defects and step up the requirements of the one pasteurized grade to a degree which will satisfy the fundamental definition of safe milk and of the one raw grade to satisfy all except the pasteurization item, we will find ourselves confronted with the difficulty that most cities will hesitate and many of them refuse to enact it into law.

There would seem to be, then, only one other possible solution, namely, to construct an ordinance with a number of grades of both raw and pasteurized milk, with the upper grade in each class sufficiently high to satisfy the most exacting reasonable requirements and with the lowest grade in each class sufficiently relaxed to leave no excuse for the least-advanced city to refuse to pass it

At this point it may be helpful to revise somewhat the first criterion of the ideal standard ordinance, which was that the ordinance must be designed to achieve the maximum percentage of milk safety. Let us subdivide this criterion as follows:

(*a*) The ordinance must be designed so as to effect the maximum percentage of pasteurization which each city will support.

(*b*) The ordinance must improve as rapidly and as much as possible the quality of the milk before pasteurization.

(*c*) The ordinance must improve as rapidly and as much as possible the quality of any portion of the milk which remains unpasteurized.

Most health officers will undoubtedly agree that a standard ordinance which satisfies these three requirements will have exhausted the practical possibilities in encouraging safe milk.

Suppose, now, that we construct a standard ordinance which describes a number of grades of both raw and pasteurized milk, which, in part, bases the grading of pasteurized milk upon the excellence of the milk pasteurized, which allows the individual city to specify which grades of milk must be pasteurized and which grades shall be barred from the market, and which is prefaced by a foreword advising the city to require as nearly complete pasteurization as local opinion will support. Such an ordinance will have the following characteristics:

(1) It will achieve the maximum percentage of pasteurization which each city will support.

(2) It should improve the quality of the raw milk which is pasteurized as rapidly and as much as possible. (Since the grading of the pasteurized product is based partly upon the grade of the milk pasteurized, and the pressure of the buying public will be in the direction of the highest grade.)

(3) It should improve as rapidly and as much as possible the quality of any portion of the milk which remains unpasteurized. (If raw milk of more than one grade is permitted to be sold, the demand will be for the highest grade)

(4) It should encourage greater milk consumption, because even in cities where lower grades of milk are permitted to be sold the fact that the highest grade is available and recognizable should insure confidence in milk quality, which in turn should increase the demand.

(5) It should appeal to most cities, as it is sufficiently flexibly designed to fit itself to the varying intensities of opinion concerning pasteurization and to the varying states of advancement in milk control. The cities which have become sufficiently converted to pasteurization can require all grades to be pasteurized, and the cities which have reached the zenith of milk-control progress can bar all grades of milk from the market except grade "A" pasteurized. In this latter case the mere description of the lower grades can, with profit, be retained in the ordinance, as violations will probably arise from time to time of such minor nature as to make the health officer hesitate to bar the milk from the market immediately and altogether. In these cases he can resort to de-grading under the ordinance as a temporary punitive measure.

The ordinance adopted by the United States Public Health Service for use in its unification program is of the above grading-type. How many grades should be provided for in the standard ordinance, and what general requirements should be specified for each grade?

Careful consideration has led to the belief that it will be wise to provide for the following grades in the Standard Ordinance in order to meet all of the conditions which a standard ordinance is required to fulfill:

(a) *Grade "A" pasteurized milk* —This grade should be milk which has been produced in a cleanly manner and under all major safety precautions, and which has been properly pasteurized in a properly designed and operated plant. This grade of milk is therefore provided with a factor of safety of 2 It should be considered and recommended by the health officer as the safest grade of milk.

(b) *Grade "B" pasteurized milk* —This grade should be milk which has been produced in the absence of certain production precautions, such as tuberculin testing of cows or health examinations of employees, but in a cleanly manner,

and which has been properly pasteurized in a properly designed and operated plant. This grade of milk will therefore be provided with a factor of safety of 1.

It is necessary to provide for this grade because, as previously indicated, the majority of cities will not support an ordinance which limits the sale of milk to grade "A" pasteurized For example, many will not support compulsory tuberculin testing of all cows or compulsory medical examination of all farm employees, and yet those cities should be encouraged to pass a standard ordinance which will at least differentiate for the buying public the milk which does not comply with these items from that which does.

(*c*) *Grade "C" pasteurized milk*—This grade should comprise all pasteurized milk not complying fully with either "grade 'A' or grade 'B' pasteurized" requirements It is included in the Standard Ordinance because some cities and authorities feel that milk supplies can be brought to a high grade more adroitly and with less friction by a policy of de-grading than by a prohibition and court case policy Again, some cities and authorities feel that even after all of the milk supply of the city is of "grade 'A' or grade 'B' pasteurized" quality it is far easier and just as effective to punish occasional lapses by degrading than through the method of "closure" Furthermore, certain thoughtful State health officers feel that it will be wise to include this grade because many city health officers can be induced to punish by de-grading, whereas they will hesitate to go to the extreme of closing, and that where the only remedy is closure by forfeiture of permit many infractions will go unpunished.

It is believed to be certain that a pasteurization plant can not long endure the competitive pressure resulting from a "grade 'C'" label, and that for this reason no practical disadvantage will follow the inclusion of this grade in the Standard Ordinance As previously indicated, cities which do not wish to tolerate this grade, even for temporary punishment means, can bar it from sale altogether in the section of the ordinance designed for this purpose. The above reasoning holds also for grade "B" pasteurized milk with respect to the relative advantages of a closure policy as compared with a policy of de-grading

(*d*) *Grade "A" raw milk*—This grade of milk should be the highest grade of raw milk which it is practicable to produce It should meet certain production refinements, such as a very low bacterial count, a very low cooling temperature, and certain structural refinements which most authorities believe can not be practicably required in the production of grade "A" pasteurized milk.

This grade of milk is included in the Standard Ordinance because, as previously stated, most cities can not be induced to pass an ordinance requiring universal pasteurization

(*e*) Finally, the grades of raw milk acceptable for each of the three grades of pasteurized milk should be defined in the ordinance and can conveniently be termed "B," "C," and "D."

These grades will also be useful for smaller communities which have no pasteurization plants and which can not be induced to require all raw milk to be of grade "A" raw quality There are many such small communities, as experience in securing the passage of milk legislation has amply demonstrated. The fear need not be entertained that such cities will, as a result, tend to have much low-grade raw milk on the market Competition under the grading principle, if properly enforced, will usually result within a very short time in practically all of the milk reaching a "grade 'A' raw" level. On the other hand, stubborn insistence upon a policy or standard ordinance which would permit the sale of only "grade 'A' raw" milk in such hesitant cities would in many cases have led to failure to pass any ordinance, and hence failure to achieve the result above noted.

The second part of the Public Health Service unification program was to encourage the adoption of the Standard Ordinance by States and cities

This part of the program is now well under way. As previously indicated, 10 States have adopted the Public Health Service ordinance as standard and nearly 100 cities have enacted it into law.

Experience in securing the enactment of this ordinance has suggested a number of items of policy.

The first is that it is unwise to ignore the dairy industry in securing the passage of milk legislation. The legislation should not be approached with the implied attitude that most of the dairymen in the community are guilty of consciously foisting a dangerous product upon the consumers, and that what is needed is some drastic law to whip them into line. The legislation should not be held out as a device to force the dairymen to do what they would otherwise be unwilling to do, but rather as a device through which a dairyman can profit financially in direct ratio to the safety of his product.

The second item of policy is that the dairymen should not be told that the ordinance is being submitted for their vote of approval or disapproval, and that it will be introduced only if a majority vote of approval is secured. Such a policy would place the milk sanitation welfare of the consumers more completely in the control of the dairy industry than is warranted. After all, the consumers should have the power to choose the kind of milk they wish to buy, and the health officer is the direct representative of the consumers.

A good plan seems to be to advise the dairymen in meeting that the local health department has determined to ask the city to pass the United States Public Health Service Standard Milk Ordinance, but that as a courtesy to the dairymen it wishes to discuss the ordinance with them first, in order that its advantages to the industry may be clear and in order to give any individual dairyman ample opportunity to register a protest with the city authorities if he so desires. It may be emphasized that the principal reason for the conference between the health department and the dairy industry is to make clear to the latter the fact that the interests of the consumers and the interests of the dairy industry are really identical, in that both need insurance against milk-borne epidemics and in that both will profit by the consumption of more milk; further, that the standard ordinance is designed to accomplish both of these objects and that both the consuming public and the dairy industry should therefore be interested in promoting its passage.

The third item of policy is that the dairymen should be advised from the outset that whether or not the city adopts the Standard Milk Ordinance the health department must necessarily take the position that pasteurized milk is safer than raw milk. If this is not made clear to the dairymen at the outset they will have the feeling,

after the ordinance is in force and the health officer gives preference to pasteurized milk, that the health departmenth as misled them and this should by all means be avoided

The next item of policy is that the development of public opinion in favor of the milk ordinance should not be begun until after the ordinance has been informally discussed with the city authorities, otherwise the city authorities are likely to feel that the ordinance is being forced upon them.

A wise plan seems to be to discuss the ordinance with the city authorities at the outset and to make clear (1) that the health department recommends the passage of the Standard Milk Ordinance, (2) that it is desired to pass the ordinance without political embarrassment to the administration, and (3) that it is the plan of the health department, in case the administration fears political embarrassment, to develop favorable public sentiment and thus insure against political embarrassment.

The third part of the Public Health Service unification program was to develop a plan of relationship between cities, States, and the Public Health Service which would promote the uniform and effective enforcement of the standard ordinance

The mere enactment of a milk ordinance by a city does not guarantee enforcement. It is believed to be a conservative statement that at present the majority of cities do not effectively enforce their milk ordinances. There are four principal reasons for this: (1) Lack of adequate personnel and funds; (2) political interference; (3) lack of confidence on the part of the public in the soundness and tenability of the local ordinance, (4) lack of sustained interest on the part of the local health officer and the public

Lack of adequate personnel and funds is frequently a reflection of one or more of the other three factors If a community is not convinced as to the soundness of its milk regulations, if there is a political desire to hamper its enforcement, or if the local health officer is not interested in its enforcement, it will follow naturally that the necessary funds will not be applied to its enforcement. It is seldom actually true that a community can not actually afford adequate milk control. An average of 6 to 10 cents per capita per year is usually sufficient for enforcement, and it is probably safe to say that if a community is convinced of the desirability of milk control it will be willing to spend this amount upon it. Therefore the destruction of this barrier to enforcement would seem logically to lie in convincing the community of the necessity for proper milk control and of its practicability. It is believed that the community can be convinced if it is possible to lay before it a concrete measure of its inferior milk sanitation as compared with the excellence of milk sanitation in other

communities which appropriate adequate funds and use the proper methods

The second barrier—political interference—is frequently the result of opposition on the part of the dairy industry, operating through political powers which are probably more often than we suspect sincerely convinced that certain features of the local milk ordinance are not necessary or sound On the other hand, political barriers are sometimes purely political and not based upon lack of conviction.

Where the first condition exists the solution would seem to be to provide an ordinance in which the dairy industry will have confidence. It is believed that a standard ordinance of wide usage would be more likely to inspire such confidence than would a local ordinance.

In the few cases in which the second condition prevails, the most effective deterrent would be a periodic rating system which would automatically bring before the voting public the evil results of political interference with the operation of a good milk ordinance.

The third barrier to enforcement—lack of public confidence in the soundness and tenability of the local ordinance—will probably disappear in the city which adopts a standard ordinance operating successfully in a large number of other cities.

The fourth barrier—lack of sustained interest on the part of the local health officer and the public—exists more frequently than we suspect. Often this is due to the health officer's inability to convince himself that enforcement of his milk ordinance will lead to measurable results. He knows of no way to evaluate the results of his work and thus keep before his appropriating body an achievement which will inspire continued appropriations.

If there could be established a method by means of which the results of milk sanitation could be fairly and periodically measured, the interest of the local health officer could be awakened by the results in other cities and sustained by a periodic measurement of the improvement effected in his own city.

It is believed, therefore, that the most effective solvent of local enforcement barriers would be to set up a continuously operating plan under which the milk sanitation of cities was measured periodically. If we could establish a fair method of determining municipal milk sanitation ratings at periodic intervals, the following advantages would likely ensue:

(1) It would help the local health officer secure adequate funds and personnel in case a low rating of the city was the result of inadequate funds and personnel. In addition to emphasizing the disease hazards he could point to the poor advertising resulting from a low rating and the excellent advertising resulting from a high rating.

(2) It would tend to remove political interference where interference would be likely to lead to an official low rating evident to the voting public.

(3) It would maintain confidence on the part of the community in its milk ordinance and its health official if the milk ordinance were sound, properly enforced, and yielding a high rating.

(4) It would sustain interest in the proper enforcement of the ordinance on the part of the local health officer.

The Public Health Service unification program, therefore, includes the following two elements of relationship between the cities, the States, and the Public Health Service:

(1) The State is advised, upon adoption of the Public Health Service program, to have one of its milk-control officials visit each city in the State operating under the standard ordinance at least once during each grading period, and check the accuracy and uniformity of the inspection and the laboratory and grading methods, thus giving assurance to the city officials and to the dairy industry that uniform enforcement methods are being followed throughout the State. Among other advantages, the local health officer frequently finds this service of assistance in enabling him to resist pleas for special dispensation in grading He is able to take the position that he can not afford to make concessions, as his work will be checked by the State health department.

(2) A Public Health Service officer is detailed to each State operating under the program each year for a period long enough to coordinate the State's interpretation of the Standard Ordinance with that of the other States, and to determine jointly with the State the milk sanitation ratings of the various cities operating under the Standard Ordinance

We thus have a plan which gives the maximum assurance of continued uniform enforcement of the standard ordinance, and which gives a scientific measure once each year of the relative progress made by the various cities operating under the ordinance This leads us logically to the necessity of devising a means of measuring the result of municipal milk sanitation effort, and thus to the fourth part of the Service unification program.

The fourth part of the Public Health Service unification program was to determine a method of measuring the results of municipal milk sanitation effort

The plan devised by the Public Health Service is simple. Each item of sanitation, including both production and pasteurization items, is assigned a value which is intended to represent approximately its relative importance The credits for all items of sanitation total 1,000. In computing the milk sanitation rating for a community the credit value for each item of sanitation is multiplied by the percentage of the total milk supply of the community which complies with that item, the result being the "earned credit" for that item. The "earned credits" for all items are added and the sum is

divided by the sum of all possible credits (1,000). The result is the milk sanitation rating of the community. A 100 per cent rating means that all of the city's milk supply is both properly produced and properly pasteurized.

A subdivision of ratings has recently been inaugurated by subdividing the general rating into a production rating and a pasteurization rating, computed as follows. The total earned credits for production items are divided by the total possible credits for production items (500), and the total earned credits for pasteurization items are divided by the total possible credits for pasteurization items (500). These give, respectively, the production and pasteurization ratings.

A 100 per cent production rating means that all of the community's milk is properly produced. A 100 per cent pasteurization rating means that all of the community's milk is properly pasteurized. Thus, for a community in which pasteurization has not yet been inaugurated, the production rating might be 90 per cent, the pasteurization rating 0.0 per cent, and the combined rating 45 per cent.

Specimen milk sanitation ratings are presented in Appendix B. These are actual ratings and were determined in the routine survey work of the Public Health Service.

Preliminary observations following the application of the Public Health Service standard program

(1) The enforcement of the ordinance has been followed by an improvement in milk sanitation.

(2) The enforcement of the ordinance has been followed by an increase in the volume of market milk sales.

(3) The ordinance has elicited the support of the dairy industry.

(4) The ordinance has been enacted by many different types of cities.

The ordinance has been followed by an improvement in milk sanitation.—Table 4 shows the increase in the general milk sanitation ratings of eight Alabama cities which have now been operating under the Public Health Service ordinance long enough to make it worth while to measure results.

TABLE 4.—*United States Public Health Service milk sanitation ratings (general)*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Rating	Date	Rating	
Montgomery	January, 1923	35.6	December, 1925	59.1	66.0
Florence	March, 1924	24.5	do	48.8	99.2
Selma	do	29.1	do	47.8	64.3
Tuscaloosa	do	29.7	do	62.7	111.1
Mobile	September, 1923	27.1	do	48.2	77.8
Huntsville	March, 1924	27.0	do	67.1	148.5
Gadsden	January, 1924	28.5	do	47.1	65.3
Albany-Decatur	March, 1925	8.1	do	73.3	805.0
Averages (weighted)[1]		29.2		54.2	85.6

[1] Weighted on gallonage consumption basis

The above figures show that there has been in these eight cities an average increase of well over 80 per cent in milk sanitation since the passage of the milk ordinance. It would be unwarranted, of course, to state that no other milk ordinance would have accomplished the same improvement in the same length of time, but it is felt that it is conservative to say that the ordinance does effect a significant increase in milk sanitation if properly enforced.

In order to illustrate the relative improvement in production and in pasteurization ratings, Tables 5 and 6 are given below.

TABLE 5.—*United States Public Health Service milk sanitation ratings (production)*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Rating	Date	Rating	
Montgomery	January, 1923	67.2	December, 1925	93.9	39.7
Florence	March, 1924	49.0	do	97.5	99.0
Selma	do	58.2	do	95.5	64.0
Tuscaloosa	do	53.3	do	94.0	76.4
Mobile	September, 1923	54.2	do	96.4	77.8
Huntsville	March, 1924	54.0	do	95.2	76.3
Gadsden	January, 1924	57.0	do	94.3	65.4
Albany-Decatur	March, 1925	16.2	do	80.8	398.5
Averages (weighted)[1]		56.8		94.8	66.9

[1] Weighted on gallonage-consumption basis.

Table 5 shows that the average production improvement in the eight cities has been 66.9 per cent and that the individual production ratings for all except one of the eight cities are now well over 90 per cent, signifying that production sanitation has in these eight cities been brought to a high level within a comparatively short period of time.

TABLE 6.—*United States Public Health Service milk sanitation ratings (pasteurization)*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Rating	Date	Rating	
Montgomery	January, 1923	4.0	December, 1925	21.4	510.0
Florence	March, 1924	0	do	0	0
Selma	do	0	do	0	0
Tuscaloosa	do	6.2	do	31.3	405.0
Mobile	September, 1923	0	do	0	0
Huntsville	March, 1924	0	do	38.9	
Gadsden	January, 1924	0	do	0	0
Albany-Decatur	March, 1925	0	do	65.8	
Averages (weighted)[1]		1.6		13.5	744.0

[1] Weighted on gallonage consumption basis.

Table 6 shows that for the eight cities as a whole the pasteurization ratings were practically zero when the work began, that the percentage increase in the pasteurization ratings of four of the eight cities

has been large, but that the other four of the eight cities were in December, 1925, still without pasteurization facilities In one of these four cities a pasteurization plant has now been placed in operation and is pasteurizing all the city's supply In the other three cities sentiment is still strongly against pasteurization, but it is believed that opinion will swing more and more toward pasteurization as the educational work proceeds In the meantime the consumers are being protected as much as possible by thorough production precautions.

In the five cities in which part of the milk is now pasteurized the increase in percentage of milk pasteurized has been as follows.

Montgomery, from 17 6 per cent to 26 7 per cent.
Tuscaloosa, from 19 8 per cent to 34 6 per cent.
Huntsville, from 19.2 per cent to 41 7 per cent.
Albany-Decatur, from 0 0 per cent to 68.2 per cent
Florence, from 0.0 per cent to 100 per cent.

The application of the Public Health Service Standard Milk Ordinance has been followed by an increase in the consumption of market milk

Table 7 shows the increase in the volume and percentage of market milk sales in the eight cities previously referred to.

TABLE 7 —*Increase in market milk consumption*

City	Preenforcement		Postenforcement		Per cent increase
	Date	Gallons per day	Date	Gallons per day	
Montgomery	January, 1923	1,588	December, 1925	2,713	70.9
Florence	March, 1924	277	March, 1925	345	24.5
Selma	do	605	do	669	10 6
Tuscaloosa	do	505	April, 1925	687	36 0
Mobile	September, 1923	[1] 2,000	December, 1925	3,351	67.6
Huntsville	March, 1924	365	March, 1925	417	15.3
Gadsden	January, 1924	362	December, 1925	370	2 2
Albany-Decatur	March, 1925	177	do	220	24.3
Totals and averages		5,879		8,772	49.2

[1] Estimated

It is evident from Table 7 that the milk consumers of the eight cities are drinking one and one-half times as much milk as they did before the application of the new program. This increase in market milk consumption can not, of course, be interpreted to indicate the true increase in total milk consumption, as we are dealing with small cities in which the number of family cows is high and in which a fairly large percentage of the total milk consumed is that from private cows. However, the figures do indicate a heavy increase in market milk consumption, and this should be very attractive to the dairy industry. Obviously it would not be scientifically sound to con-

clude that this increase in consumption of milk has been caused by the application of the standard program. It is conceivable that some other cause could have been operative, but this is deemed unlikely.

The Standard Ordinance has, in general, elicited the support of the dairy industry

In a large number of the cities now operating under the Standard Milk Ordinance the passage of the ordinance was urged by the dairy industry itself.

This has been one of the most gratifying features of the work. The history of milk legislation in the past has generally been that it has been enacted over the protest of the dairy industry. The support which has been accorded the present program by the dairy industry should be accepted as evidence that that industry is progressive and is mindful of its responsibility for the health of its patrons

The support of the dairy industry is further illustrated by the indorsement given the Public Health Service program by the National Dairy Council, a national organization of the dairy interests.

Finally, the support of the dairy industry is evidenced by the fact that, so far as known, only two or three court cases have occurred in connection with milk control in all of the many cities now operating under the ordinance. None of these court cases has been decided against the city.

The Standard Ordinance has been enacted by practically all types of cities

In the 10 States which have thus far adopted the Standard Milk Ordinance the many cities which have enacted the ordinance include some of the larger cities in those States; cities with a population as small as 5,000, cities which had previously done no milk-control work whatever, cities which have spent many years in improving milk supplies; cities which are converted to 100 per cent pasteurization; and cities which are largely opposed to pasteurization.

It is believed, therefore, that it may be fairly safely stated that the ordinance is so framed as to be attractive to the majority of types of cities. None of the States in which the ordinance has become standard has cities of over 500,000 population, and it still remains for actual future experience to demonstrate whether the ordinance will be attractive or can be modified so as to become attractive to such large cities.

CONCLUSION

In general, the preliminary results discussed above should be accepted as suggestive only, and not as conclusive. It is not believed that they cover either a sufficient number or range of cities nor a

sufficient period of time to be finally conclusive. It is believed, however, that they will be of value and interest to health officers and others impressed with the necessity for a solution of our national milk-control problem.

APPENDIX A

United States Public Health Service Standard Milk Ordinance

(Modified as adopted by the Conference of State and Territorial Health Officers at Washington, D. C. May, 1926)

AN ORDINANCE

Defining "Milk" and Certain "Milk Products," "Milk Producer," "Pasteurization," etc., Prohibiting the Sale of Adulterated and Misbranded Milk and Milk Products, Requiring Permits for the Sale of Milk and Milk Products, Regulating the Inspection of Dairy Farms and Milk Plants, the Testing, Grading Labeling, Placarding, Pasteurization, Regrading, Distribution, Sale, and Denaturing of Milk and Milk Products, Providing for the Publishing of Milk Grades, the Construction of Future Dairies and Milk Plants, the Enforcement of this Ordinance, and the Fixing of Penalties

Be it ordained by the ———— of the city of ———— as follows

SECTION 1. DEFINITIONS —The following definitions shall apply in the interpretation and the enforcement of this ordinance

Milk —(A) Milk is hereby defined to be the whole, fresh, clean, lacteal secretion obtained by the complete milking of one or more healthy cows, properly fed and kept, excluding that obtained within fifteen days before and five days after calving, or such longer period as may be necessary to render the milk practically colostrum free; which contains not less than eight and one-half per cent (8½%) of solids not fat, and not less than three and one-fourth per cent (3¼%) of milk fat.

Milk fat or butter fat.—(B) Milk fat or butter fat is the fat of milk and has a Reichert-Meissel number of not less than twenty-four (24) and a specific gravity of not less than 0 905 (40° C /40° C).

Cream —(C) Cream, sweet cream, is that portion of milk, rich in milk fat, which rises to the surface of milk on standing or is separated from it by centrifugal force, is fresh and clean, and which contains not less than eighteen per cent (18%), preferably twenty per cent (20%) of milk fat; provided that cream having less than eighteen per cent milk fat shall be known as substandard cream.

Cream having less than thirty per cent (30%) milk fat shall be known as light cream.

Cream having thirty per cent (30%) or more and less than forty per cent (40%) milk fat shall be known as heavy cream, and cream having forty per cent (40%) or more milk fat shall be known as extra heavy cream.

Whipping cream and manufacturing cream are creams containing not less than 30% milk fat intended for whipping or manufacturing purposes, and the grades of same shall not be based on bacterial count.

Skimmed milk —(D) Skimmed milk is milk from which substantially all the milk fat has been removed.

Chocolate milk —(E) Chocolate milk is defined as whole or adjusted or skimmed milk to which has been added in a sanitary manner a chocolate syrup composed of wholesome ingredients, and which is labeled with the grade of milk or milk products from which it is made. If chocolate milk contains less than three and one-quarter per cent (3¼%) milk fat, the label shall indicate the percentage of milk fat to which the milk has been adjusted. (This section is optional with States.)

Buttermilk.—(F) Buttermilk is the product which remains when milk fat is removed from milk or cream, sweet or sour, in the process of churning It contains not less than eight and five-tenths per cent (8 5%) of milk solids not fat.

Cultured buttermilk—(G) Cultured buttermilk is the product resulting from the souring or treatment by a lactic acid culture of milk or milk products.

Evaporated milk (unsweetened)—(H) Evaporated milk (unsweetened) is milk from which a considerable portion of water has been evaporated and which contains not less than twenty-five and five-tenths per cent (25 5%) of milk solids and not less than seven and eight-tenths per cent (7 8%) milk fat

Condensed milk (sweetened)—(I) Condensed milk (sweetened) is milk from which a considerable portion of water has been evaporated, to which sugar has been added, and which contains not less than twenty-eight per cent (28%) of milk solids and not less than eight per cent (8%) milk fat

Condensed skimmed milk—(J) Condensed skimmed milk is skimmed milk from which a considerable portion of water has been evaporated, and which contains not less than twenty per cent (20%) of milk solids

Powdered (dried) whole milk—(K) Powdered whole milk is milk from which substantially all the water has been removed, and which contains not less than twenty-six per cent (26%) of milk fat and not more than five per cent (5%) of moisture

Powdered (dried) skimmed milk—(L) Powdered skimmed milk is skimmed milk from which substantially all the water has been removed, and which contains not more than five per cent (5%) of moisture

Recombined milk.—(M) Recombined milk is a substance produced by recombining powdered whole milk, powdered skimmed milk, condensed or evaporated whole milk, or skimmed milk, and milk fat, with water, and shall conform in milk-fat percentage and bacterial counts to the provisions of this ordinance relating to milk

Milk products—(N) Milk products shall be taken to mean and include cream, skimmed milk, adjusted milk, buttermilk, cultured buttermilk, evaporated milk (unsweetened), condensed milk (sweetened), condensed skimmed milk, powdered whole milk, powdered skimmed milk, and recombined milk.

Pasteurization—(O) The terms "Pasteurization," "Pasteurized," "Pasteurize," and similar terms shall be taken to refer to the process of heating every particle of milk or milk products to a temperature of not less than one hundred and forty-five degrees (145°) Fahrenheit, and holding at such temperature for not less than thirty (30) minutes in pasteurization apparatus approved by the health officer, the temperature and time being automatically recorded by a temperature and time recording device approved by the health officer.

Adulterated milk and milk products—(P) Any substance claimed to be any milk or milk product defined in this ordinance but not conforming with its definition as given in this ordinance shall be deemed adulterated and misbranded.

Milk producer—(Q) A milk producer is any person, firm, or corporation which owns or controls one or more cows, a part or all of the milk from which is for sale, or sold or delivered to another person, firm, or corporation. This section shall not be construed to include what is generally known as "family cows"

Milk distributor—(R) A milk distributor is any person, firm, or corporation which has in possession, offers for sale, sells, or delivers to another any milk or milk products for consumption or manufacturing purposes.

Dairy or dairy farm—(S) A dairy or dairy farm is any place or premises where one or more cows are kept, a part or all of the milk or milk products from which is sold or delivered to any person, firm, or corporation This section shall not be construed to include what is generally known as "family cows."

Milk plant.—(T) A milk plant is any place, or premises, or establishment where milk or milk products are collected, handled, processed, stored, bottled, pasteurized, or prepared for distribution.

Health officer.—(U) The health officer shall be taken to mean the health officer of the city of ———— in person, or his authorized representative.

Average bacterial count.—(V) Average bacterial count shall be taken to mean the average of the bacterial counts of all samples taken during the grading period, including at least four samples taken upon separate days.

Grading period.—(W) The grading period shall be such period of time as the health officer may designate, within which grades shall be determined for all milk and cream supplies, provided that the grading period shall in no case exceed six (6) months.

Disinfectant.—(X) A disinfectant is any germicidal substance approved by the health officer.

SEC. 2. THE SALE OF ADULTERATED OR MISBRANDED MILK OR MILK PRODUCTS PROHIBITED.—No person, firm, association, or corporation shall within the city of ———— produce, sell, offer or expose for sale, or have in possession with intent to sell any milk or milk product which is adulterated or misbranded.

SEC. 3. PERMITS.—It shall be unlawful for any person, firm, association, or corporation to bring into or receive into the city of ————, for sale, or to sell, or offer for sale therein, or to have on hand any milk or milk product, excepting evaporated milk, condensed milk, condensed skimmed milk, powdered whole milk, and powdered skimmed milk, who does not possess an unrevoked permit from the health officer of the city of ————, and on whose vehicles or in whose place of business there does not appear in a conspicuous place a placard showing the permit number in figures at least three inches high and one and one-half inches wide.

Such a permit may be revoked by the health officer upon the violation by the holder of any of the terms of this or any other health ordinance of the city of ————, provided that the holder of said permit shall, after complying with such revocation, have the right of appeal to the board of health.

SEC. 4. LABELING AND PLACARDING.—All bottles, cans, packages, and other containers enclosing milk or any milk product defined in this ordinance shall be plainly labeled or marked with (1) the name of the contents as given in the definitions in this ordinance; (2) the grade of the contents if said contents are graded under the provisions of this ordinance, (3) the word "pasteurized" if the contents have been pasteurized; (4) the word "raw" if the contents are raw; (5) name of producer or distributor. The label or mark shall be in letters of a size and kind approved by the health officer and shall contain no marks or words not approved by the health officer.

Every grocery store, restaurant, café, soda fountain, or similar establishment selling or serving milk shall display at all times, in a place designated by the health officer, a card furnished by the health officer, stating the grade of the milk at the time when delivered and whether same is raw or pasteurized, and including the following statement: *The Safest Grade of Milk is Grade "A" Pasteurized*.

SEC. 5. INSPECTION OF DAIRY FARMS AND MILK PLANTS FOR THE PURPOSE OF GRADING OR REGRADING.—At least once during each grading period the health officer shall inspect every dairy farm producing milk or cream for consumption within the city of ————, and all milk plants whose milk or cream is intended for consumption within the city of ————. In case the health officer discovers the violation of any item of sanitation, he shall make a second inspection after a lapse of such time as he deems necessary for the defect to be remedied but not before the lapse of three days, and the second inspection shall be used in

determining the grade of milk or cream. Two violations of this ordinance within any one grading period shall call for immediate de-grading

One copy of the inspection report shall be posted by the health officer in a conspicuous place upon an inside wall of one of the dairy farm or milk plant buildings, and said inspection report shall not be removed by any person except the health officer Another copy of the inspection report shall be filed with the records of the health department

SEC 6 THE TESTING OF MILK AND MILK PRODUCTS—During each grading period at least four samples of milk or cream from each dairy farm and each milk plant shall be tested by the health officer. Samples of milk and cream from stores, cafés, soda fountains, restaurants, and other places where milk products are sold shall be tested as often as the health officer may require Bacterial counts shall be made in conformity with the plate-count method of the standard methods recommended by the American Public Health Association. Tests may include such other chemical and physical determinations as the health officer may deem necessary for the detection of adulteration Notices of bacterial counts shall be given to the producer or distributor concerned as soon as made, or to any interested person on request Samples may be taken by the health officer at any time prior to the final delivery of the milk or milk products All stores, cafés, restaurants, soda fountains, and other similar places shall furnish the health officer, upon his request, with the name of the milk distributor from whom their milk is obtained

Should the market value of any single sample exceed twenty-five cents the city of ———— shall pay the distributor therefor

SEC. 7 THE GRADING OF MILK AND CREAM—At least once every six (6) months the health officer shall announce through the press the grades of all milk and cream supplies delivered by all producers or distributors and ultimately consumed within the city of ————. Said grades shall be based upon the following standards, the grading of cream being identical with the grading of milk.

Certified Milk

Certified milk is milk which conforms with the requirements of the American Association of Medical Commissions, and is produced under the supervision of the Medical Milk Commission of the Medical Society of ———— County, and of the State Board of Health or City or County Health Officer.

Grade "A" Raw Milk

Grade "A" raw milk is milk the average bacterial count of which as determined under section 6 of this ordinance does not exceed 50,000 per cubic centimeter, and which is produced upon dairy farms conforming with all of the following items of sanitation.

Cows Tuberculosis and other diseases—(1) A physical examination and tuberculin test of all cows shall be made before any milk therefrom is sold, and at least once every twelve months thereafter by a veterinarian approved by the health officer or by the State livestock sanitary authority, and said tests shall be made, and any reactors disposed of, in accordance with the current requirements approved by the United States Bureau of Animal Industry for accredited herds

A certificate signed by the veterinarian and filed with the health officer shall be the only valid evidence of the above test. Every diseased animal shall be removed from the herd at once and no milk from diseased cows shall be offered for sale All reacting animals shall be isolated at once and immediately excluded from the premises All animals failing to pass the T B test shall be branded with the letters "T" or "TB" on the shoulder, hip, or jaw, and removed at once and slaughtered under the direction of the health officer Each letter in the brand shall be not less than two inches high and one and one-half inches wide.

Dairy barns.—(2) Lighting. Such sections of all dairy barns where cows are kept or milked shall have at least three square feet of window space for each stanchion.

(3) Air space. Such sections of all dairy barns where cows are kept or milked shall have at least five hundred (500) cubic feet of air space per stanchion, and shall be well ventilated.

(4) Floors. The floors and gutters of such parts of all dairy barns in which cows are kept or milked shall be constructed of concrete or other equally impervious and easily cleaned material approved by the health officer and shall be graded to drain properly, and shall be kept clean and in good repair. No horses, pigs, fowl, etc., shall be permitted in parts of the barn used for dairy purposes.

(5) Walls and ceilings. The walls and ceilings of all dairy barns shall be whitewashed once each year or painted once every two years, or finished in a manner approved by the health officer, and shall be kept clean and in good repair. In case there is a second story above that part of the barn in which cows are kept or milked, the ceiling shall be tight.

(6) Cow yard. All cow yards shall be graded and drained as well as practicable and kept clean.

(7) Manure disposal. All manure shall be removed and stored or disposed of in such manner as best to prevent the breeding of flies therein.

Milk house or room.—(8) Construction. There shall be provided a separate milk house or milk room for the handling and storage of milk and the washing and sterilizing of milk apparatus and utensils, provided with a tight floor constructed of concrete or other impervious material and graded to provide proper drainage. The walls and ceilings of the milk house or room shall be of such construction as to permit easy cleaning, and shall be painted at least once each year or finished in a manner approved by the health officer. The milk house or room shall be well lighted and ventilated and all openings effectively screened to prevent the entrance of flies, and shall be used for no other purpose than the handling and storage of milk or milk products and other operations incident thereto. The cleaning and other operations shall be so located and conducted as to prevent any contamination one to the other. The milk room shall not open directly into the barn or into any room used for sleeping or domestic purposes.

(9) Cleanliness and flies. The floors, walls, ceilings, and equipment of the milk house or room shall be kept clean at all times. All means necessary for the elimination of flies shall be used.

(10) Toilet. Every dairy farm shall be provided with a sanitary toilet constructed and operated in accordance with the ordinances of the city of ——————.

(11) Water supply. The water supply shall be easily accessible, adequate, and of a safe sanitary quality.

Utensils.—(12) Construction. All containers or utensils used in the handling or storage of milk or milk products must be made of non-absorbent material and of such construction as to be easily cleaned, and must be in good repair. Joints and seams shall be soldered flush. All milk pails shall be of a narrow-mouth design approved by the health officer.

(13) Cleaning. All containers and other utensils used in the handling, storage, or transportation of milk and milk products must be thoroughly cleaned after each usage.

(14) Sterilization. All containers and other utensils used in the handling, storage, or transportation of milk or milk products shall between each usage be sterilized with steam or chlorine or in a manner approved by the State health authority.

(15) Storage: All containers and other utensils used in the handling, storage or transportation of milk or milk products shall be stored so as not to become contaminated before again being used.

(16) Handling After sterilization no container or other milk or milk product utensil shall be handled in such manner as to permit any part of the person or clothing to come in contact with any surface with which milk or milk products come in contact.

Milking.—(17) Udders and teats The udders and teats of all milking cows shall be clean at the time of milking

(18) Flanks· The flanks of all milking cows shall be kept free from visible dirt at the time of milking

(19) Milkers' hands· Milkers' hands shall be clean, rinsed with a disinfectant, and dried with a clean towel immediately before milking Should the milking operation be interrupted, the milkers' hands must be redisinfected Wet hand milking is prohibited Convenient facilities shall be provided for the washing of milkers' hands

(20) Clean clothing· Milkers and milk handlers shall wear clean outer garments while working

(21) Milk stools Milk stools shall be kept clean

(22) Removal of milk Each pail of milk shall be removed immediately to the milk house or straining room No milk shall be strained in the dairy barn.

(23) Cooling Milk must be cooled within one hour after milking to 50 degrees Fahrenheit or less and maintained at or below that temperature until delivery, unless it is delivered to a milk plant for pasteurization or separation, in which case it must be cooled or pasteurized within two hours of the time of production

(24) Bottling and capping Capping shall be done by machine Caps shall be purchased in sanitary tubes and kept therein in a clean place until used

Personnel.—(25) Health certificates Every person connected with a dairy or milk plant whose work brings him in contact with the production, handling, storage, or transportation of milk or milk products shall have within twelve months passed a medical examination made by the health officer.

(26) Notification of disease Notice shall be sent to the health officer immediately by any milk producer or distributor upon whose dairy farm any case of sickness or any infectious, contagious, or communicable disease occurs

Grade "B" Raw Milk

Grade "B" raw milk is milk the average bacterial count of which at no time prior to delivery exceeds 200,000 per cubic centimeter, or which falls in class 1 as determined by the reductase test as described in the Standard Methods of Milk Analysis of the American Public Health Association, and which is produced upon dairy farms conforming with all the items of sanitation required for grade "A" raw milk except (2), (3), (4), (5), or (6), provided that cleanliness of the barn and cow yard shall in no case be omitted Item (23) shall apply except that the cooling temperature shall be changed to sixty (60) degrees Fahrenheit.

Grade "C" Raw Milk.

Grade "C" raw milk is milk the average bacterial count of which at no time prior to delivery exceeds 1,000,000 per cubic centimeter, or which falls in class 2 as determined by the reductase test as described in the Standard Methods of Milk Analysis of the American Public Health Association, and which is produced on dairy farms conforming with all the items of sanitation required for Grade "B" raw milk, except (1), (7), (12), (14), (23), (24), or (25), provided that cleanliness shall in no case be omitted.

Grade "D" Raw Milk.

Grade "D" raw milk is milk which does not meet the requirements of grade "C" raw milk, and the average bacterial count of which does not exceed 5,000,000 per cubic centimeter, or which falls in class 3 as determined by the reductase test as described in the Standard Methods of Milk Analysis of the American Public Health Association.

Grade "A" Pasteurized Milk

Grade "A" pasteurized milk is grade "A" or grade "B" raw milk which has been pasteurized, cooled, and bottled in a milk plant conforming with all of the following items of sanitation and the average bacterial count of which at no time after pasteurization and until delivery exceeds 50,000 per cubic centimeter.

Buildings and equipment.—(1) Floors The floors of all rooms in which milk is handled shall be constructed of concrete or other equally impervious and easily cleaned material and shall be smooth, properly drained and provided with trapped drains, and kept clean.

(2) Walls and ceilings Walls and ceilings of rooms in which milk is handled or stored shall be frequently painted with a light-colored paint or finished in a manner approved by the health officer and kept clean

(3) Doors and windows All openings into the outer air shall be effectively screened to prevent the access of flies Doors shall be self-closing

(4) Lighting and ventilation: All rooms shall be well lighted and ventilated

(5) Protection from contamination and flies. The various milk-plant operations shall be so located and conducted as to prevent any contamination one to the other All means necessary for the elimination of flies shall be used This requirement shall be interpreted to include separate rooms for (*a*) the pasteurizing, cooling, and bottling operations, (*b*) the container-washing and sterilizing operation Cans of raw milk shall not be unloaded directly into the pasteurizing room.

(6) Toilet facilities: Every milk plant shall be provided with toilet facilities conforming with the ordinances of the city of ————. There shall be at least one room or vestibule not used for milk purposes between the toilet room and any room in which milk or milk products are handled or stored. The doors of all toilet rooms shall be self-closing. Toilet rooms shall be kept in a clean condition, in good repair, and well ventilated. In case privies or earth closets are permitted and used, they shall be located at least 100 feet from the building, and shall be of a sanitary type constructed and operated in conformity with the ordinances of the city of ————.

(7) Water supply. The water supply shall be easily accessible, adequate, and of a safe, sanitary quality.

(8) Washing facilities Washing facilities shall be provided, including hot running water, soap, and sanitary towels of a type approved by the health officer. The use of a common towel is prohibited.

(9) Milk piping. Only "sanitary milk piping" of a type which can be easily cleaned with a brush shall be used.

(10) Construction of equipment All equipment with which milk comes in contact shall be constructed in such manner as to be easily cleaned.

(11) Disposal of wastes: All wastes shall be disposed of in conformity with the requirements of the health officer.

Methods. (12) All milk containers and milk apparatus shall be thoroughly cleaned after each usage and sterilized in a manner approved by the health officer immediately before each usage.

(13) Storage of containers: After sterilization all bottles, cans, and other containers shall be stored in such manner as to be protected from contamination.

(14) Handling of containers and apparatus: Between sterilization and usage all containers and apparatus shall be handled in such manner as to prevent any part of the person or clothing from coming in contact with any surface with which milk or milk products come in contact.

(15) Storage of caps: Milk-bottle caps shall be purchased and stored only in sanitary tubes and shall be kept therein until used.

(16) Pasteurization Pasteurization shall be performed as described in the definition section of this ordinance. The time and temperature records charts

shall be dated and preserved for a period of three months for the information of the health officer.

(17) Cooling All milk not pasteurized within two hours after it is received at the plant shall then be immediately cooled to a temperature of 50 degrees Fahrenheit or less and maintained thereat until pasteurized, and all pasteurized milk shall be immediately cooled to a temperature of 50 degrees Fahrenheit or less and maintained thereat until delivery.

(18) Bottling Bottling shall be done in automatic machinery approved by the health officer in such manner as to prevent any part of the person or clothing from coming in contact with any surface with which milk or milk products come in contact

(19) Overflow milk· Overflow milk which has become machine contaminated shall not be sold for human consumption

(20) Capping: Capping shall be done by machinery approved by the health officer Hand capping is prohibited

(21) Time of delivery Milk to be consumed in the form of whole milk shall be delivered to the final consumer within 36 hours of the time of pasteurization

Personnel—(22) Health certificates· Every person connected with a dairy or milk plant whose work brings him or her in contact with the production, handling, storage, or transportation of milk or milk products shall have within twelve months passed a medical examination made by the health officer

(23) Notification of disease: Notice shall be sent to the health officer immediately by any milk producer or distributor upon whose dairy farms or in whose milk plant any case of sickness or any infectious, contagious, or communicable disease occurs

(24) Cleanliness All persons coming in contact with milk or milk-products containers or equipment shall wear clean outer garments and shall keep their hands clean at all times while thus engaged

Grade "B" Pasteurized Milk:

Grade "B" pasteurized milk is grade "A," "B," or "C," raw milk which has been pasteurized, cooled, and bottled in a milk plant conforming with all of the items of sanitation required for grade "A" pasteurized milk excepting (2), (4), or (24), and the average bacterial count of which at no time after pasteurization and prior to delivery exceeds 100,000.

Grade "C" Pasteurized Milk·

Grade "C" pasteurized milk is pasteurized milk which does not meet the requirements of grade "B" pasteurized milk, and the average bacterial count of which at no time prior to delivery exceeds 500,000 per cubic centimeter.

SEC 8. GRADES OF RAW MILK WHICH MUST BE PASTEURIZED—The wording of this section should be adjusted to the degree of support which the community will accord pasteurization. If a pasteurization plant is already in existence, or can be established, and the majority of the voting public can be educated to support complete pasteurization, this section should read as follows:

"At the expiration of twelve months from the date on which this ordinance takes effect, and thereafter, all grades of milk sold in the city of ———— shall be pasteurized before delivery to the consumer."

Other communities in which a pasteurization plant exists or can be established, but in which the prevailing sentiment can not easily be converted to complete pasteurization, should be urged to limit the sale of raw milk to grade "A" raw milk after the lapse of one year.

Communities which can not be induced to adopt even this second alternative may permit lower grades to be sold raw, but should keep constantly in mind, as they make progress under this ordinance, the desirability of achieving complete pasteurization as soon as possible.

SEC. 9.—SUPPLEMENTARY REGRADING.—At any time between regular announcements of milk grades any producer or distributor may make application for regrading his product.

In case the applicant's existing low grade is due to excessive bacterial count, said application must be supported by at least two bacteriological examinations made subsequent to the end of the previous grading period and indicating that the quality of the applicant's output has improved since the last grading announcement and conforms with the requirements of a higher grade. The samples upon which the said two analyses are made may be brought to the health department laboratory by the applicant.

Upon the receipt of a satisfactory application, the health officer shall make at least four bacteriological analyses upon samples collected by the health officer of the applicant's output within a period of not less than two weeks and not more than three weeks of the date of the application. The health officer shall award a higher grade immediately in case the said four analyses indicate the necessary quality.

In case the applicant's existing low grade is due to a violation of an item of sanitation other than bacterial count, said application must be accompanied by a statement signed by the applicant to the effect that the violated item of sanitation has been conformed with. Within one week of the receipt of such an application the health officer shall make a reinspection of the applicant's establishment and, in case the findings justify, shall award a regrade.

At any time between regular announcements of milk grades the health officer may lower the grade of any milk producer or distributor if, as a result of inspection or milk analyses, a lower grade shall be justified in accordance with the terms of this ordinance.

SEC. 10. TRANSFERRING OR DIPPING MILK.—No milk producer or distributor shall transfer milk or milk products from one container to another upon the street or in any vehicle or store, or in any place except a bottling or milk room especially used for that purpose, except as may be specially permitted by the health officer in the case of milk being delivered in bulk. The sale of dip milk is hereby expressly prohibited.

It shall be unlawful for hotels, soda fountains, restaurants, and similar establishments to sell or serve any whole milk or adjusted milk except in the original container in which it was received from the producer or distributor.

SEC. 11. MILK NOT TO BE PASTEURIZED OUTSIDE OF ———— COUNTY.—No milk or cream shall be sold in the city of ———— that has been pasteurized outside the county of ————, except as may be authorized by the health officer.

SEC. 12. SPITTING.—No person shall spit, except into a receptacle provided for the purpose, in any part of any room, vehicle, or other place used for the sale, storage, handling, or transportation of milk.

SEC. 13. VEHICLES.—All vehicles used for delivery of milk in the city of ———— shall be so constructed as to protect the milk from the sun and from contamination. Such vehicles shall be kept clean while used in transporting milk or milk products. No substance capable of contaminating milk or milk products shall be transported with milk or milk products in such manner as to permit contamination.

SEC. 14. DENATURING MISBRANDED PRODUCTS.—The health officer shall immediately denature with rennet or some harmless coloring matter any milk or milk product found misbranded with respect to grading or sold without a permit.

SEC. 15. REPASTEURIZATION PROHIBITED.—No milk or milk products shall be pasteurized more than once.

SEC. 16. FUTURE DAIRIES AND MILK PLANTS.—All dairies and milk plants from which milk is supplied to the city of ————, which are hereafter constructed,

shall conform in their construction to the requirements of the health officer, which shall not be less than the grade "A" requirements of this ordinance

SEC 17 PROSCRIBED MILK —Milk which does not conform with the following grades as described in this ordinance shall not be sold in the city of ———— ———— (Any city which wishes to prohibit the sale of any of the grades of milk described in this ordinance may use this section for that purpose)

SEC 18. PENALTY.—Any person, firm, association, or corporation who shall violate any provision of this ordinance shall be fined not more than one hundred dollars ($100), at the discretion of the recorder

SEC 19 REPEAL AND DATE OF EFFECT —All ordinances and parts of ordinances in conflict with this ordinance are hereby repealed; and this ordinance shall be in full force and effect immediately upon its adoption and its publication, as provided by law

SEC 20 UNCONSTITUTIONALITY CLAUSE —Should any section, paragraph, sentence, clause, or phrase of this ordinance be declared unconstitutional or invalid for any reason, the remainder of said ordinance shall not be affected thereby Each and every violation of the provisions of this ordinance shall constitute a separate offense

APPENDIX B

UNITED STATES PUBLIC HEALTH SERVICE

Determination of Municipal Milk Sanitation Rating for City of Huntsville, Ala., as of March, 1924—Population, 10,000

Computation of ratings

	Per cent
Production rating—earned production credits÷possible production credits=(475.17)÷(500)	95.0
Pasteurization rating—earned pasteurization credits÷possible pasteurization credits =(249.36)÷(500)	49.87
Combined rating—earned production and pasteurization credits÷1,000 (724.53)÷(1,000)	72.5

HUNTSVILLE, ALA., *April, 1926.*

PUBLIC HEALTH ENGINEERING ABSTRACTS

Many School Water-Supplies Found Unsatisfactory. Anon. *Public Health News, New Jersey State Department of Health*, vol. 11, No. 4, March, 1926, pp 92–95. (Abstract by E. C. Sullivan.)

More than half of 740 school water-supplies recently examined by the bureau of chemistry of the State Department of Health of New Jersey showed evidence of contamination and were classified as unsuitable for drinking purposes. This conclusion is based upon complete chemical and bacteriological examinations made, at the request of the State Department of Public Instruction, upon samples submitted by representatives of local boards of health or education. Wells, springs, and cisterns were included in the survey, embracing all types of water used in schools not receiving water from an approved public system.

Report of Committee on Mosquito Control of Sanitary Engineering Section of American Public Health Association, October 21, 1925 *American Journal of Public Health*, vol. 16, No 3, March 26, 1926, pp 258–262. (Abstract by J. A LePrince.)

This report is a summary of antimosquito activities in the United States for the year Control operations were carried on very generally in 11 States, to a limited extent in 10 States, and no control work was done in 27 States.

In New Jersey the wet and humid weather shortened the usual larval development period by two or three days, and in the Southern States the rain shortage caused marked increases in *Culex* production, owing to intensified sewage pollution of streams In New Jersey the expenditure for mosquito control was $325,000. The ditching machine now developed for use on the New Jersey marshes weighs 12 tons, has a ground pressure of only 1½ pounds per square inch, and "chews" up the sod and spreads it over an area 30 feet wide. Experiments indicate a cutting speed of 40 feet per minute and the cost per linear foot of ditch (regulation straight-sided ditch adopted as the standard in that State) as somewhat less than one-half cent.

The Florida State Antimosquito Association had a bill passed in the legislature enabling any county to organize a mosquito control district.

In Mississippi, 40 towns did control work, and in Texas, 100 communities, in addition to 68 towns on the Texas border, are engaged in *Stegomyia* control Alabama has been doing mosquito control for ten years; work is going on in 23 counties, and $33,000 was spent last year. In addition to work in rural sections of Georgia, 40 towns carried on campaigns against mosquitoes.

In California, 17 mosquito abatement districts are active, in Virginia, 25 towns are doing mosquito control work, and in Rhode Island the State has aided several communities in financing mosquito control operations. In Illinois, in Chicago and Cook County, an intensive antimosquito campaign was inaugurated by the Gorgas Memorial Institute in which boy scouts made house-yard inspections. Mosquito production was found on 40 per cent of the premises

The United States Department of Agriculture has started investigations of the salt marsh mosquito problem of the Gulf Coast. The Cotton Belt and Missouri Pacific railways are working in cooperation with cities and towns along their lines, and an antimosquito demonstration was recently conducted under the joint auspices of the Missouri Pacific Railway, Arkansas State Bankers Association, and the State Health Department of Arkansas.

Anopheles control work in the United States was started by the United States Public Health Service in 1914 in 13 States, and is now supervised by the State health departments, but the requests for advisory assistance from incorporated communities are coming in so rapidly that some State health departments can not keep up with the requests owing to insufficient personnel.

Report of Committee on Transportation of Milk and Milk Products. Russell S Smith, International Association of Dairy and Milk Inspectors *Fourteenth Annual Report,* October 12, 14, 1925, pp. 135–150 (Abstract by W. W. White)

Some of the conditions in handling milk causing economic losses which were brought to the attention of the President's Agricultural Committee by Secretary Hoover are outlined. The changes in methods of transporting milk in recent years, with an explanation of the extent of these changes, are thoroughly explained Insulated glass-enamel lined metal tanks in insulated cars are used for bulk shipments. Tanks are mounted on special cradles and anchored to the needle beam of the car. This means of transportation can be

used only where a railroad siding is available. The unit tank system was tried by railroads hauling milk to New York City, but it failed because of insufficient equipment to handle the weight.

Motor truck tanks and trailers are a recent development, and up to January 1, 1925, about 230 metal tanks were in use To avoid overweight on roads in some States semitrailers or trailers are used.

Refrigerator trucks are the latest means of hauling milk from receiving stations to the city plants. Condenser coils, compressor and compressor-motor drive are located on top of the refrigerator body.

A committee of the United States Chamber of Commerce studied the motor transportation situation and in their conclusions recommended cooperation among transportation agencies at points where further expansion would be possible Short hauls by organized motor transports will reduce yard congestion and release cars for line hauls Further development of technical equipment and public regulation of all common carriers will be necessary to insure good service.

The great improvement in transportation directs special attention to the efforts which are being made by some to reach perfection in the sanitary production, handling, and transportation of milk and milk products.

DEATHS DURING WEEK ENDED JULY 17, 1926

Summary of information received by telegraph from industrial insurance companies for week ended July 17, 1926, and corresponding week of 1925 (From the Weekly Health Index, July 21, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended July 17, 1926	Corresponding week, 1925
Policies in force	64, 955, 791	60, 539, 284
Number of death claims	12, 203	10, 541
Death claims per 1,000 policies in force, annual rate	9. 8	9. 1

Deaths from all causes in certain large cities of the United States during the week ended July 17, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925. (From the Weekly Health Index, July 21, 1926, issued by the Bureau of the Census, Department of Commerce)

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended July 10, 1926, 37 States reported 954 cases of diphtheria. For the week ended July 11, 1925, the same States reported 883 cases of this disease. Ninety-nine cities, situated in all parts of the country and having an aggregate population of more than 29,000,000, reported 549 cases of diphtheria for the week ended July 10, 1926. Last year for the corresponding week they reported 505 cases. The estimated expectancy for these cities was 628 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles—Thirty-four States reported 5,336 cases of measles for the week ended July 10, 1926, and 1,967 cases of this disease for the week ended July 11, 1925 Ninety-nine cities reported 1,757 cases of measles for the week this year, and 1,058 cases last year.

Poliomyelitis—The health officers of 37 States reported 37 cases of poliomyelitis for the week ended July 10, 1926. The same States reported 90 cases for the week ended July 11, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 1,803 cases; last year, 1,103 cases; 99 cities—this year, 682 cases; last year, 477 cases; estimated expectancy, 367 cases.

Smallpox.—For the week ended July 10, 1926, 37 States reported 310 cases of smallpox. Last year for the corresponding week they reported 305 cases. Ninety-nine cities reported smallpox for the week as follows: 1926, 42 cases; 1925, 90 cases; estimated expectancy, 56 cases One death from smallpox was reported by these cities for the week this year—at Omaha, Nebr.

Typhoid fever—Six hundred and twenty-eight cases of typhoid fever were reported for the week ended July 10, 1926, by 36 States. For the corresponding week of 1925 the same States reported 1,016 cases of this disease. Ninety-nine cities reported 76 cases of typhoid fever for the week this year and 186 cases for the corresponding week last year. The estimated expectancy for these cities was 131 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 93 cities, with a population of more than 28,350,000, as follows; 1926, 388 deaths; 1925, 328.

City reports for week ended July 10, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[2] Dengue, 1 case at Charleston, S. C.

The following table gives the rates per 100,000 population for 103 cities for the five-week period ended July 10, 1926, compared with those for a like period ended July 11, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 103 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,-750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, June 6 to July 10, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

Kwantung						
Port Arthur	0	0	0	0	1	0

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

British India—Chittagong, Cochin, Tuticorin, Vizagapatam.
Ceylon—Colombo
Federated Malay States.—Port Swettenham.
Straits Settlements—Penang
Dutch East Indies—Batavia, Samarang, Cheribon, Belawan Dli, Palembang, Sabang, Makassar, Menado, Banjermasin, Balik-Papan, Tarakan, Pontianak, Padang
Sarawak.—Kuching
British North Borneo—Sandakan.
Portuguese Timor.—Dilly.
Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.
French Indo-China.—Turane.
Formosa—Keelung.
Kwantung—Dairen.
Japan—Nagasaki, Yokohama, Moji, Kobe, Niigata, Tsuruga, Hakodate, Simonoseki.
Korea.—Chemulpo, Fusan
Manchuria.—Antung, Mukden, Changchun, Harbin.
U. S. S. R.—Vladivostok.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.
New Guinea.—Port Moresby.
New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia.—Noumea.
Fiji.—Suva.
Hawaii.—Honolulu.

AFRICA

Egypt.—Alexandria, Port Said, Suez.
Anglo-Egyptian Sudan.—Port Sudan.
Eritrea.—Massaua.
French Somaliland.—Jibuti.
British Somaliland.—Berbera.
Italian Somaliland.—Magadiscio.
Kenya.—Mombasa.
Zanzibar.—Zanzibar.
Tanganyika.—Dar-es-Salaam.
Seychelles.—Victoria.
Portuguese East Africa.—Mozambique, Beira, Lourenço Marques.
Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from:

British India.—Karachi.
Mauritius.—Port Louis.
Madagascar.—Tamatave, Majunga.

CANADA

Communicable diseases—Province of Ontario—May 30–June 26, 1926 (comparative).—During the four week period ended June 26, 1926, communicable diseases were reported in the Province of Ontario, Canada, as follows:

Disease	May 30–June 26, 1926		May 31–June 27, 1925	
	Cases	Deaths	Cases	Deaths
Cerebrospinal meningitis	5	1	5	2
Chancroid			1	
Chicken pox	454		457	1
Diphtheria	188	12	142	12
German measles	433		23	
Gonorrhea	65		132	
Influenza		20	10	7
Lethargic encephalitis			4	4

Disease	May 30–June 26, 1926		May 31–June 27, 1925	
	Cases	Deaths	Cases	Deaths
Measles	2,976	12	1,063	2
Mumps	37		300	
Pneumonia		159		126
Poliomyelitis	2			
Scarlet fever	373	3	326	1
Smallpox	36		12	1
Syphilis	72		48	
Tuberculosis	184	77	165	85
Typhoid fever	33		46	3
Whooping cough	290	6	297	7

Smallpox.—The greatest number of cases of smallpox was reported at Kingston, viz, 7. At North Bay and at Peterboro 6 cases each were reported; in Richmond township, 4 cases.

CHINA

Shanghai—Cholera—July 20, 1926.—Thirty-five cases of cholera with 8 deaths, were reported from Shanghai, China, July 20, 1926.

ECUADOR

Plague—Guayaquil—June 16–30, 1926—During 15 days ended June 30, 1926, one case of plague was reported at Guayaquil.

Plague-infected rats—During the period under report 10,037 rats were reported taken and 13 rats found plague infected.

GREECE

Plague—Patras—June 5–12, 1926.—Under date of June 12, 1926, two cases of plague were reported as having occurred at Patras, Greece, June 5 and 12, 1926, respectively. The occurrence was in different quarters of the city

PUBLIC HEALTH REPORTS

ISSUED WEEKLY

BY THE UNITED STATES
PUBLIC HEALTH SERVICE

VOLUME 41 :: :: NUMBER 32

AUGUST 6 - - - 1926

SPECIAL ARTICLES

WASHINGTON
GOVERNMENT PRINTING OFFICE
1926

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B. J. LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain. (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of diesase. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

FOOD POISONING FROM A STREPTOCOCCUS IN CHEESE

By B A LINDEN, W R TURNER, and CHARLES THOM, Microbiological Laboratory, Bureau of Chemistry, United States Department of Agriculture [1]

Two outbreaks of food poisoning attributed to cheese have been reported within the year March, 1925–Feburary, 1926. One outbreak involving nine persons at Biddeford, Me, was reported in March, 1925, as attributable to eating an imported Albanian cheese. The second outbreak of apparently 22 cases in Kansas City, Kans, was reported in February, 1926. The cheese suspected of causing the second outbreak was an American cheddar manufactured in Wisconsin.

The reports of the attending physicians in both cases were so similar and our bacteriological findings were such that they may be reported in one paper.

CASES

In the first outbreak, Dr. C. J. Xaphes, of Biddeford, Me., was called to attend nine persons suffering from what he diagnosed as food poisoning. The symptoms as given briefly by him are as follows. "Pains in stomach, severe vomiting, diarrhea, expression dull, and pulse fast." His investigation of the food eaten by those affected showed that cheese was a principal component of the single meal which all had taken together. None of the actual food consumed was available; but, since suspicion was placed on the cheese, samples from the same lot were obtained and forwarded to the Microbiological Laboratory of the Bureau of Chemistry.

The cases in the second outbreak reported in February, 1926, were very similar. Dr. H. L. Dwyer, of Kansas City, in reporting the 18 cases which he treated, gave the following descriptions "The symptoms manifested were referable to the stomach and intestines, and were characterized by nausea and vomiting, paroxysms of abdominal pain, and diarrhea The nature of the symptoms and the sudden attack in so many individuals suggested a common cause, probably related to some dietary factor Investigation along this line revealed the fact that all the affected persons partook of some

[1] The authors acknowledge the cooperation of the Hygienic Laboratory of the United States Public Health Service, which furnished animals and space for an essential check series of feeding experiments

cheese and this was the only food substance which was eaten by everyone of those affected." A sample of the cheese actually used was obtained and forwarded to the Microbiological Laboratory.

Physical examination of the samples of cheese submitted from the first outbreak showed it to be extremely hard, with an apparently high salt content, which was evident by the appearance of salt crystals on cut surfaces of the samples. The percentages of moisture and salt found by the Food Control Laboratory in these samples, together with the aerobic counts per gram made from plate cultures on dextrose agar are given in Table 1.

TABLE 1

Sample	Per cent of moisture	Per cent of salt	Bacterial counts	Sample	Per cent of moisture	Per cent of salt	Bacterial counts
A	25 09	5 50	2,000,000	D	24 90	7 20	500,000
B	25 16	5 84	600,000	E			200,000
C	24 39	7 37	300,000				

From suitable colonies transfers were made to dextrose agar slants and smears prepared for miscroscopic examination From approximately 100 colonies thus examined cocci were the only group found, and of these but five proved to be members of the *Streptococcus lactis* type. Members of the paratyphoid-enteritidis group, so commonly reported to be the cause of such outbreaks,[2] were not found.

The presence of such large numbers of cocci in a type of cheese with a long ripening period and a high concentration of sodium chloride in the water present seemed significant. This organism was, therefore, isolated and used for feeding experiments. When fed to white rats, rabbits, guinea pigs, and sheep, no apparent harmful effects were noted. More or less disturbance was produced when milk cultures were fed to dogs. Cats when fed milk cultures gave positive results. For these experiments, flasks containing 100 c. c. of sterile milk were inoculated and incubated at 37° C. for three days. Upon feeding this culture to a cat, diarrhea was produced within four hours. This abnormal condition continued for four days. The original organism was recovered from the stools of this animal for three days following the first disturbance. Cultures of the organism recovered, when grown in milk and fed to a second cat, produced the same gastric disturbances in 8 to 10 hours. A third cat fed the original isolated cultures gave the same positive results.

On account of the seemingly high acid production in milk cultures, it was deemed advisable to observe animals fed "soured" milk.

[2] Numerous epidemiological and bacteriological discussions of such outbreaks are scattered through the literature of the past five years.

Flasks of milk "soured" with a culture of *Streptococcus lactis* were used. Three feedings of this material failed to produce any abnormalities in the experimental animals.

Experimental work was interrupted from June, 1925, until the occurrence of the second outbreak in February, 1926 The cultures used in the work already reported were found to be dead, but the organism was again isolated from the original cheese, which had remained in the refrigerator. Although the cheese was heavily incrusted with salt, the organisms remained viable and did not appear to have lost virulence by the storage.

The sample submitted from the second outbreak was taken directly from the cheese held responsible for the poisoning. Aerobic plates on dextrose agar made from this sample showed 27,000,000 bacteria per gram of cheese Of these, approximately 20,000,000 were cocci which were morphologically and culturally identical with those isolated from the Albanian cheese. A number of examinations failed to reveal the presence of members of the paratyphoid-enteritidis group of organisms. Accordingly the organism from the Albanian cheese was reisolated, as already indicated, and the two strains were carried parallel in further experimental work.

Results of the experiments conducted the previous year had indicated that cats were more susceptible than any other type of animal tested. A number of cats were placed under observation for several days to determine the normal consistency of the stools when the animals were fed a normal diet of meat, bread, and milk. After the preliminary observation period, a single feeding of inoculated milk was introduced, followed by return to the regular diet. Previous experiments had shown that the introduction of such a feeding of fresh or sour milk had no disturbing effect upon the cats.

For these experiments flasks containing 150 c. c. of sterile skim milk were inoculated with the cheese organism. Incubation at 37° C. for 48 hours caused the milk to curdle, and after this time feedings were conducted. Table 2 shows the results of nine feeding experiments Cultures A_1 indicate the strain isolated from the Albanian cheese, D_1 the Wisconsin cheese. Culture C_2S_2 fed to cat No. 7 was a culture recovered from the stool of cat No. 1 and grown in milk.

TABLE 2

Animal No	Culture	Diarrheic stools within—	Normal stools after—	Animal No	Culture	Diarrheic stools within—	Normal stools after—
			Days				*Days*
1	A_1	3 stools within 16 hours	5	6	A_1	24 hours	6
2	A_1	Animal failed to eat culture		7	C_2S_2	5 hours	4
3	A_1	24 hours	6	8	D_1	24 hours	5
4	D_1	48 hours	6	9	D_1	do	6
5	D_1	do	6				

From Table 2 it is seen that this organism when grown in milk and fed to cats causes a gastro-intestinal disturbance. The feces from these animals were exceedingly watery and of a light color as contrasted with the normal hard, dark-colored excreta. It is interesting to note that the culture (C_2S_2) recovered from the feces of a previous feeding caused the gastro-intestinal disturbance in a much shorter time than any of the other cultures. Recovery from the effects of the feedings required about six days in the majority of cases.

While cultural studies were being made, it was observed that chopped-beef medium acted as an excellent substratum for the growth of the organism. To test beef as a basis for poisoning outbreaks of this kind, jars containing 100 grams of chopped meat and 3 ounces of broth were inoculated and incubated for 24 hours at 37° C. By the end of this incubation period luxurious growth had been produced. Three cats were fed with such cultures, including both strains, but no positive gastro-intestinal disturbance occurred. The experiment was repeated with three more cats, but again there was no evidence of enteric disturbances.

Similar flasks were prepared and inoculated with retransfer after each three days of incubation until the sixth transfer. These cultures were fed to two cats, but no disturbance was produced. Organisms from these meat cultures, including strains A_1 and C_2S_2, were then transferred back to milk and retransferred at three-day intervals six times and the sixth series of milk cultures were fed to three cats. Diarrhea developed in all three animals in approximately eight hours.

Thus far, therefore, no sickness has been produced in these experiments except when milk was used as a culture medium.

Cultures of the organisms isolated from the two types of cheese were studied and the following description is prepared from the results obtained. These studies were identical for the organisms from the two sources; therefore but one description is necessary.

DESCRIPTION OF THE ORGANISM

MORPHOLOGY

Form: The organism was spherical, regardless of the type of media used for its growth.

Size: The cells had a diameter of from 0.8 to 1.2 micron.

Arrangement: The organisms were generally arranged in pairs or short chains. In milk cultures, pairs were the usual type. In beef infusion medium cultures, short chains of 6 to 8 cells predominated.

Motility: Motility was never observed.

Staining reaction: The organism was found to be Gram positive, regardless of the age of the culture.

CULTURAL CHARACTERISTICS

Agar streak: On dextrose agar, growth was rapid, beaded, raised, smooth, glistening, grayish, white opaque. Growth on beef extract agar was somewhat less rapid than on dextrose agar.

Agar colonies: On dextrose agar, plates showed growth within 24 hours at 37° C. The colonies formed were small, round, grayish white, amorphous, undulate-edged, slightly raised on the surface of the medium, and small, grayish white, lens-shaped subsurface.

Gelatin stab: Growth was uniform throughout the length of the stab without any liquefaction.

Bouillon: A uniform turbidity with no sediment was produced.

Potato: Potato cultures showed no evidence of growth

Dunham's solution: A flocculent growth was produced, with no formation of indol

Nitrate broth: Uniform cloudiness was produced, with no reduction to nitrates.

Litmus milk: Reduction of the litmus was evident after 24 hours' incubation at 37° C. After 48 hours, evidence of acid production was shown by the production of a reddish ring at the surface. Soft coagulation was produced after three to four days.

BIOCHEMICAL FEATURES

Gas production: Gas production was not evident in bouillons containing various fermentable substances.

Acid production: Acid production in milk after a long incubation showed the production of 0.5 to 0.6 per cent acid, calculated as lactic. Bouillon containing dextrose, maltose, lactose, sucrose, salicin, mannite, rhammose, and glycerol showed acid production, but with raffinose and inulin no acid was produced.

Oxygen relation: The organism was facultative.

Temperature relation: Minimum for growth, 16° C.; optimum, 37° C.; maximum, 42° C

The occurrence of these organisms in cheese, together with their reaction in experimental animals fed milk cultures, makes significant their relation to the common pasteurization temperatures. Consequently, experiments were conducted using the temperatures of 138°, 142°, and 145° F. Tubes containing 9 c c. of sterile skim milk were allowed to heat to the desired temperature in the constant temperature bath and were then inoculated with 1 c. c. of a bacterial suspension. At intervals of five minutes the tubes were removed, cooled in ice water, and 1 c. c. quantities plated. Total counts were made after 24 hours' incubation at 37° C. At 138° F. no apparent effect was produced. Table 3 shows the results of these experiments.

TABLE 3

Temperature	142° F	145° F	Initial count	3,500,000	1,000,000
Time exposed	Summary of surviving bacteria		Time exposed	Summary of surviving bacteria	
5 minutes	2,570,000	223,850	20 minutes	400,000	50
10 minutes	760,000	7,000	25 minutes	160,000	0
15 minutes	550,000	500	30 minutes	6,800	0

From Table 3 it is seen that 142° F. has some effect upon the organisms. However, for complete sterilization, 145° for 30 minutes is considered necessary.

The organism involved has not been identified certainly as any well-described species. Morphologically it has much in common with the ordinary lactic types used in the preparation of "starters" for butter and cheese making, although the concentration of acid produced (0.5 to 0.6 per cent by titration, calculated as lactic) is considerably lower than that sought in the usual lactic "starters." The organism could be carried as a contamination of such starters without easy means of detecting its dangerous character. Its ability to grow readily in many substrata leaves many avenues open by which this species may reach human food.

These outbreaks and the confirmatory experiments described are reported here without attempting to generalize too broadly. Barber [2] reported similar experiments with cocci and similar results upon human subjects. The recent literature of food poisoning and food infections has failed to recognize organisms other than those of the paratyphoid-enteritidis group as involved in causing these acute enteric disturbances. Nevertheless, such outbreaks are exceedingly frequent and such studies as have been possible have very commonly yielded negative results. It may well be that the description of the organism found in these samples, together with the cultural methods described, may lead to the recognition of other outbreaks from this type of organism.

REPORT OF A SURVEY TO DETERMINE THE MALARIA PREVALENCE IN THE OKEFENOKEE SWAMP

By BRUCE MAYNE, Associate Entomologist, United States Public Health Service

The Okefenokee Swamp is situated in Charlton and Ware Counties, in southeast Georgia, and extends into northeast Florida, covering about 660 square miles. The general level of the swamp is from 114 to 120 feet above tidewater. At ordinary stages of water it discharges into the Gulf of Mexico near Cedar Keys through the Suwanee River

[2] Barber, M. A.: Milk Poisoning Due to a Type of *Staphylococcus albus* Occurring in the Udder of a Healthy Cow. Philippine Jour. Sci., 9: 515, 1914.

but in wet weather overflow water reaches the Atlantic through the St. Mary's River.

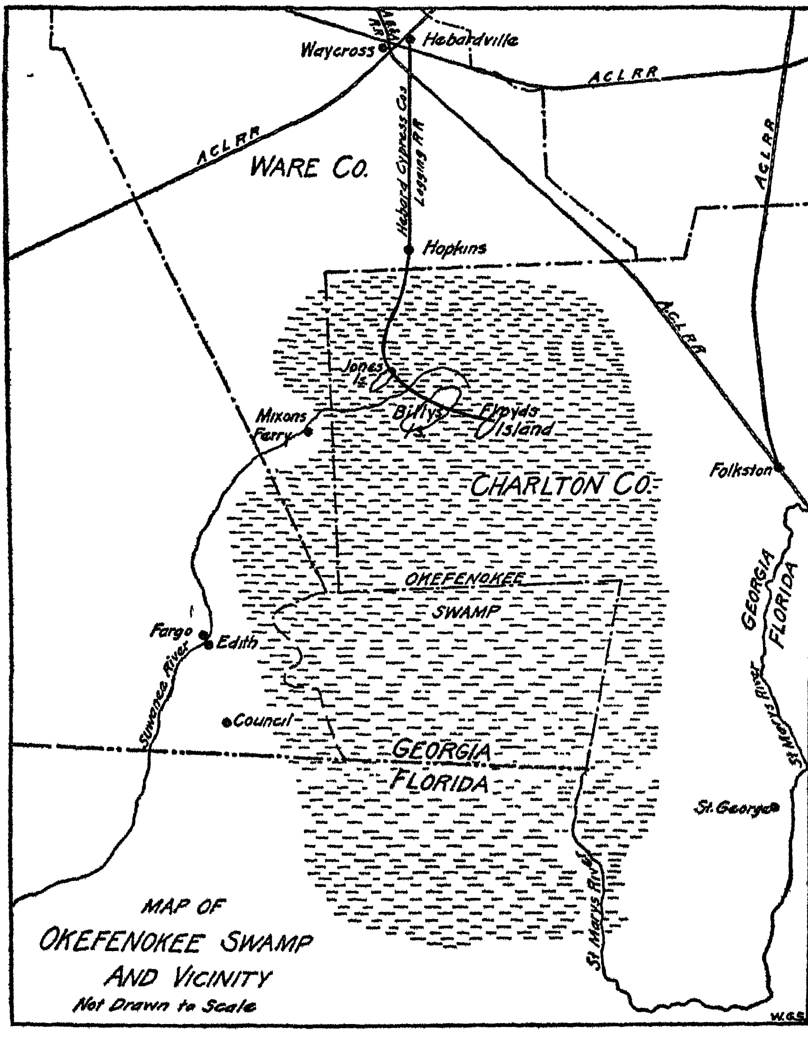
Where the sand rises a little above the water there are islands covered with open forests. The largest islands in the swamp, Floyds, Billys, Jones, and Black Jack are covered with pine, palmetto, and cypress on their higher portions. On the borders of these islands there is a low hummock land which sustains a vigorous growth of such timber as magnolia and oak in rich, sandy soil. Outside of these growths of timber are dense thickets of small shrubs and matted bamboo briers and beyond is an open marsh covered with water lilies and long bushes, the thick roots of which afford the only support for the feet in wading through the soft ooze and mud, which yields to the weight of a man so that he may sink to his armpits in many places. Forests of cypress, black gum, and other moisture-loving trees grow in the muck of the swamp; and where the muck is several feet deep trees are absent or nearly so, making open marshes known locally as "prairies" The prairies, some of which have an area of several square miles, are mostly in the eastern part of the swamp Many small islands and clumps of trees, "houses," dot these prairies, and they are generally surrounded by a floor of moss (*Sphagnum* moss) forming a floating surface over the water. Often the surface moss does not break through beneath the feet of the walker, and he can then see it sink and rise for several yards at every step, hence its Indian name, Oke-fe-no-kee, or trembling earth

The first recorded survey of the swamp was made in 1857, with a view to ascertaining the practicability of draining it. An extensive drainage canal, abandoned by the builders, still remains to bear witness to these futile attempts During the past 40 years numerous explorations of the great swamp have been made, chiefly by hunting parties, timber surveyors, and naturalists.

On August 22, 1924, a survey of the Okefenokee Swamp was instituted by the United States Public Health Service to determine the prevalence of malarial fevers and mosquitoes, with a laboratory and office installed at Billys Island, the field headquarters of the Hebard Cypress Co. This company leased the swamp lands for the timber rights and colonized the habitable portions with a view to permanent occupation. Billys Island is 5 miles long and 1 mile wide. The principal settlement was situated about 15 miles in the interior of the swamp. It housed about 450 people and accommodated the following domestic animals: 105 cattle, 3 mules, 162 swine, and approximately 1,000 fowls. An impression of the permanence of the settlement may be gained by a list of buildings that were maintained in addition to the usual company railroad workshops and structures incidental thereto. Office, general store, confectionery store, drug store, negro schoolhouse and church, white schoolhouse and church,

motion-picture theater, four bathhouses, two boarding houses, and a hotel. This survey was continued the following year, in August, 1925, making a total of 70 days devoted to the complete investigation.

Factors considered in the survey.—The surrounding waters at Billys Lake and the edge of the swamp were surveyed for aquatic forms in



order to locate the source of *Anopheles* propagation. The usual inspection of houses and animal quarters and outhouses was undertaken, and observations were made of mosquitoes biting in the open. Mosquitoes collected inside dwellings were dissected when the residents gave a history of even remote or doubtful malaria. Blood

specimens were collected from similar sources, and in a few instances spleen palpations were made in addition. A malaria history index was made, and the economic conditions of the residents were studied intensively.

The prevalence of anophelines and their habits —The following facts have been noted: The only anopheline present was *A. crucians*, which was found inside of dwellings as well as on porches and under houses. *A. crucians* was commonly attracted by artificial light, and found to attack usually in the presence of bright electric lights. This species was seen biting in daylight, in sunshine as well as shade, near lake or swamp water, beginning as early as 7.15 a. m. In one experiment *A. crucians* was found abundantly in a poorly screened shack, biting at night and escaping before daylight. It was conclusively demonstrated during both visits to the swamp that this species freely entered houses, only a small proportion remaining until daylight after a nocturnal invasion. A specific instance of this is related as follows

While attending a social party at a private home on Billys Island I observed specimens of *A. crucians* attacking persons seated inside the house. I counted 18 persons who were being annoyed by the biting of mosquitoes, and during the course of 40 minutes I collected and identified 212 specimens of *Anopheles crucians*. On the following morning, at 6 30 a. m., an inspection of this residence showed only 14 specimens of *crucians* inside the dwelling and 142 specimens on the gallery resting on rafters and walls.

Anopheles crucians was found on Billys Island, Jones Island, and Floyds Island in great numbers. On Billys Island it far outnumbered all other species of mosquitoes. An idea of its prevalence and distribution is given in the following typical figures from the catch of two localities:

Where taken	Residence of Mr A	Residence of Mr B
Inside of house	92	12
Veranda and under house	139	1,502
Privy	36	6
Smokehouse and c[illegible]house	20	40
Cow stable	346	197

In the wooded area invasion of tree stumps and hollow logs by *A. crucians* is very common. Over 200 specimens, all *A. crucians*, were collected from one hollow log near Billys Lake. Here also in the course of 20 minutes 35 specimens of *A. crucians* were collected in the act of biting the investigator.

Relation of temperature to biting.—Here, as elsewhere, a definite relation was noted as to the effect of temperature on mosquito

biting habits. In this regard the relations of humidity as influenced by swamp environments were observed to have no marked effect. The following data are presented:

Observation No 1, August 22, 1925—8 p m outdoor temperature, 72.5° F. on veranda of house Here for period of one hour no biting was experienced. A change was made to the room with windows closed, where the temperature registered 78° F In the course of one hour eight specimens of *crucians* were collected in the act of biting a companion and myself

Observation No 2, August 15, 1925—Every evening up to this time note was taken of the number of *crucians* attacking persons in and about houses on the island The temperature had been registering a mean maximum of 82° F., and infestation with *crucians* was constant and noticeable Beginning August 16 to 18 there was a temperature drop to 73° F from 7 p m to 12.15 a m, during which time there was an entire absence of biting from *A crucians*. Five persons in various homes in the swamp reported the marked difference, and confirmed the impressions of the writer as to the correlation of decline in temperature and change in biting habits of the *crucians*. Beginning with the evening of August 18, normal warm temperature prevailed and the mosquito attacks were resumed as formerly.

Numerous isolated observations were made during the two summers' investigations tending to confirm the conclusion that, under conditions found present in the swamp, biting by *A. crucians* never occurred with temperatures under 72° F.

History of the reported absence of malaria in the Okefenokee Swamp.—This particular region was selected for investigation because of the repeated claims of visitors to the swamp of the perpetual freedom from malaria. Doctor Reavis, the physician of the Hebard Cypress Co., had practiced medicine continually in the Okefenokee Swamp and vicinity for 6 years, and was familiar with the case records of his predecessors for an additional 10 years. He asserted quite positively that malarial fevers in this region were unknown in acute and chronic forms.

Settlers born in the swamp or intimately acquainted with conditions there for periods of 25 to 40 years declare that chills and fever were never present to their knowledge. Many of these men served as guides and hunters for various scientists who in the past 20 years have visited the region for purposes of collecting specimens and for biological study.

Several leaders of camping parties furnished the information that no case of malarial fever resulted from exposure to bites of harassing swarms of anopheline mosquitoes during several years of occasional visits. Trappers and woodsmen in this region were not acquainted with any case of suspicious symptoms of malaria originating in the swamp. Mr. Hopkins, former field manager of the Hebard Cypress Co., reported having spent three years with 12 to 15 men in a survey party visiting all sections of the swamp without a single instance of complaint of malarial symptoms.

Doctor Armistead, the physician at the town of Hopkins, the first settlement north of the swamp, who is the company doctor for the Twin Tree Lumber Co., reported that the cases of malarial fever observed in that town were contracted in the towns of Council and Leesburg, Ga. He had never seen a case of chills and fever on Jones Island, the property in the swamp operated by the Twin Tree Lumber Co., among a working force of 320 to 375 men

Malaria history index.—On account of the reputed absence of the disease, it was deemed necessary to proceed circumspectly in the manner of obtaining individual histories from residents of the swamp. With this in view a history index was obtained with the following results:

Year	Number of persons	Report
1924	435	Negative
1925	558	Do

Blood specimens obtained.—As many blood specimens as possible (347) were collected in the course of the investigation. These were taken at the company physician's office, in the company commissary store, and at private homes. "Thick smears" were made, and whenever there was any complaint of fever or previous history of suspicious malarial symptoms a thin smear was obtained in addition to the thick-smear blood specimen.

Results of study of histories and blood examinations.—During the two seasons of the investigation no plasmodia were found in an intensive study of the 347 blood films examined. About 34 persons gave a history of having had malaria within the preceding four years, and in every instance they claimed to be free from symptoms at the time of this investigation. Examination of the blood of these persons did not reveal malaria parasites. None of these persons was taking treatment for malaria at the time of the investigation

A few specific instances of histories of such people are cited:

One household of seven persons, who formerly resided at Owens Ferry on the Saltillo River, in Georgia, asserted that they had been malaria sufferers for years, that they had never missed two months without clinical symptoms They had lived in the Okefenokee Swamp 18 months and had never experienced chills or other evidence of their former complaint. I examined all seven of these persons, and all appeared negative for malaria.

In 1919, 6 years previous to this investigation, a party of eight people had entered the employ of the Hebard Cypress Co , after a six weeks' stay at Council, Ga , where they suffered severely with malarial fevers. None of these people complained of a recurrence of symptoms up to the time I made blood examinations and found them negative microscopically.

One year prior to this investigation two families of nine persons had entered Billys Island after spending 10 months with frequent spells of chills and fever in a malarious section of northwest Florida Not one of these people showed enlarged spleens or plasmodia on examination during the present investigation.

Observations on mosquito incidence.—It seemed rather anomalous that in the presence of innumerable adult *Anopheles* so few larvae were observed. Numerous excursions were made in small boats, covering approximately 30 miles of navigable water throughout the swamp territory, when only a few aquatic forms of *Anopheles* were encountered The larvae collected were few in number, never more than three-fourths grown They were found in open swamp less than 1 mile south of Billys Island; on the shore line in protected coves of Billys Island, along the grass-lined banks of the headwaters of the Suwanee River, and in flotage in Big Water Lake 14 miles east of Billys Island

Top-feeding minnows, *Gambusia* and *Fundulus*, were present in abundance The wooded swamp sections and portions of Billys Lake and "The Canal" were matted with *Sphagnum* moss The open waters, "the prairies," were canopied with a species of water lily, or "bonnets" In these environments mosquito larvae or pupae were never found

Adult mosquitoes were collected from various natural habitats and in the region of settlements during these studies as follows:

Year	Total	Female	Male	Species
1924	4,282	4,249	33	*A crucians*
1925	6,528	6,476	52	Do

A total collection of 10,810 specimens were examined with a hand lens, and in every instance no other species but *A. crucians* was identified. No specimen of *quadrimaculatus* was encountered in the swamp area. These mosquitoes, exclusive of the 85 males, were found distributed in the following resting places:

Location	Number of specimens	Percentage
Inside of dwellings	1,180	11
Porch and under dwellings	1,609	15
Privy	965	9
Outhouses	613	6
Mule and cow stable	5,577	52
Fowl house	751	7

House infestation by *A. crucians* in occupied dwellings was common. As many as 520 specimens were collected from the interior and gallery of one four-room house.

There seems to be a correlation between the small number of males found and the scarcity of larvae. There were only 85 males in a total of 10,810 specimens collected, giving a proportion of 1 male to 127 females *A. crucians*. This suggests, in addition to the absence of larvae or lack of propagation, the probability of the production of definite broods with little or no overlapping in generations, a condition not found commonly elsewhere.

Inasmuch as it appeared to be an established fact that *Anopheles quadrimaculatus* was never found in the swamp, the query arose as to the possibility of this species becoming established when introduced from the outside. Only one experiment was attempted bearing on this subject. A specimen of *quadrimaculatus* captured at the town of Hopkins was brought to the swamp laboratory. It was induced to bite the observer and placed in a suitable jar for development. Two days later the specimen was killed after having laid about 20 eggs in water obtained from the swamp, and 18 larvae were produced. These were allowed to develop for six days and then destroyed.

SUMMARY

No malarial fevers were found in the area known as the Okefenokee Swamp on the border between Florida and Georgia.

In the limited time of the investigation a history index was made of 993 persons. Blood examinations were made of 347, in whom no plasmodia were found. *Anopheles crucians* was the only species of mosquito found in a collection of 10,810 specimens. Of these, 307 specimens were dissected with negative results.

SURVEY OF THE SETTLED AREA SURROUNDING THE SWAMP

Several settlements and towns bordering on the swamp were visited and inquiries were made relative to malaria incidence. Investigations were made of the following.

Hopkins, situated 15 miles north of Billys Island, with a population under 1,000. This town was the mill center of the Twin Tree Lumber Co., and the railroad junction for the Hebard Cypress Co. Here in 1924 malaria was found sporadically, in every instance introduced. Several cases were traced to Leesburg, Ga , and Council, Ga. In 1925 there were no cases observed Collections of *Anopheles* were made here in both years, when great numbers of mosquitoes were found. *Anopheles crucians* predominated at all times. A few specimens of *A. quadrimaculatus*, in the ratio of 1 to 160 *crucians*, were collected in both years of the investigation.

Suwanee Lake Ranch, 2 miles west of Hopkins, housing 16 persons. Numerous *Anopheles crucians* were observed and collected, and malaria histories taken. No evidence of malaria was noted.

Mixon's Ferry, on the headwaters of the Suwanee River, 10 miles west of Billys Island Here 18 people lived in a secluded community engaged in agriculture and fishing Two days were spent here and information was obtained ruling out malaria either recent or remote. Anopheline mosquitoes were found to be extremely numerous. I collected 312 specimens of *A crucians*

On the eastern border of the swamp the region was surveyed as far south as Folkston and St George, about 35 miles from Waycross. This locality is 6 miles from the border of the swamp, and has a population of about 2,800 people. The records of the local physician practicing here for five years indicated the entire absence of malarial fevers on the southern edge of the swamp. This was also confirmed in a malaria history survey. The only anopheline mosquito observed here was *crucians*, in moderate numbers. About 600 specimens of *crucians* were collected from this locality.

Edith, a settlement of about 100 people, 30 miles southwest of Billys Island and on the east bank of the Suwanee River, about [illegible] miles from the swamp. Malaria was not present at the time of my visit, and records of 25 years signified the absence of malarial fevers In a collection of *Anopheles* from this place two *quadrimaculatus* and 258 *crucians* were observed.

Fargo, situated directly across the river from Edith, with a population of 400. No histories of malaria were obtained here. There were collected 357 *crucians* and 3 *quadrimaculatus*.

Council, Ga., a lumber-mill town of 800 people, situated 38 miles from Billys Island Here malarial fevers were reported as very serious. The company physician had treated 78 cases of bedridden malaria patients within eight months At the time of my visit there were 18 cases under treatment. A collection of 112 specimens yielded 16 *A. quadrimaculatus*.

CHOLERA IN BANGKOK AND THE WORK OF THE SIAMESE RED CROSS

According to the latest reports, the cholera epidemic continues in Bangkok, Siam. From May 2 to 22, 1926, there were reported 944 cases of cholera with 508 deaths in Bangkok, 362 cases with 192 deaths being reported for the week ended May 22.

Information has been received from official sources that, in view of the continuation of the epidemic, attacks have been made on the Red Cross Society of Siam by two Siamese newspapers, which have stated that the society has not given sufficient aid in combating the outbreak and is not cooperating with the public health department or does very little in comparison with the activities of that department.

In a recent communication the American minister at Bangkok gives the information that, in view of such charges, the Siam Red Cross Society has issued a statement signed by H. R. H. Prince Nagor Svarga, vice president of the society, who states that the articles appearing in the two newspapers were marked by ignorance of the facts and were not meant to convey friendly advice; that the council of the Red Cross Society does not care to dispute with any newspaper or newspaper writer, but, as such articles might mislead the people and lessen their trust in the Red Cross, it has been thought well to make the following reply:

1. As to the aims of the Red Cross, the society was not established to do work which would in any way compete with the work of Government officials. The Red Cross is designed to be a support to the Government Some of its work it does hand in hand in agreement with the Government; some of its work it does of its own initiative; but there is no competition.

2. Fighting an epidemic of disease is quite special work, and if that work is undertaken in different ways and not under the direction of one head, good results are impossible; in fact, serious harm might be caused For that reason, in relief work in time of any public calamity, or in fighting an epidemic of disease, when Government officials have entered on the work, Red Cross societies all over the world must place themselves under the directions of the Government officials and act under their orders. In this particular case the department of public health represents the Government for the purpose of this work The Red Cross Society, therefore, does its work, in this connection, along the lines prescribed by and under the direction of the department of public health. No independent action is taken.

3. From the beginning of this cholera epidemic many months ago, the Red Cross Society has been in close touch with and has acted according to the requirements of the department of public health. For example, the society began making anticholera vaccine without bringing up any question of cost. Then, when the epidemic became worse at the beginning of the present year, the Red Cross Society had two meetings with the officials of the public health department. The duties of the bodies were then divided most amicably so as to cover the whole field

4. The department of public health at the same time expressed a wish that the supply of vaccine should be increased to 25,000 cubic centimeters a day. That was ten times the former quantity, but the Red Cross supplied the new requirements, though it meant working by night as well as by day. This vaccine has to be prepared with the utmost care; any mistake might be dangerous to the people. Throughout, the department of public health has found the supply sufficient and correctly prepared.

5. For the vaccine supplied to the department of public health since the beginning of the year and to be supplied until the epidemic subsides, the Red Cross has agreed to charge the department nothing. It is part of the contribution of the Red Cross toward fighting the epidemic, and it is costing something like 100,000 ticals a month.

6 The Red Cross makes provision for inoculating all persons coming to its various institutions and sends doctors to people's houses for the same purpose This is done without any charge being made

7. When the amount of vaccine produced had suddenly to be increased tenfold, the supply available for doctors and dispensaries was stopped for a few days; but that supply is again available as before. It was felt that it was more important to maintain the supply by which everybody could be inoculated free of charge than to sell to private practitioners.

TYPHOID OUTBREAK AND ANTITYPHOID CAMPAIGN IN COLON, PROVINCE OF MATANZAS, CUBA[1]

Early in December, 1925, there occurred a case of sickness in Colon which was diagnosed as malaria by the local health officer. Under this supposition the patient was permitted to be moved to a different part of the town. Like many other homes in Colon, this new home was provided with a pit latrine which was connected with an unused well. The city obtains its water supply from a great number of wells, all fed by the same underground stream as are the unused wells employed for the deposit of excreta.

Within 10 or 12 days of the patient's arrival, 20 new cases of typhoid fever occurred in the immediate vicinity of his house, all verified first clinically and later bacteriologically as positive for typhoid fever—evidently a clear-cut case of water-borne infection

Unfortunately, this outbreak was not reported to the Federal health authorities. It appears that the infection was next carried to a private waterworks system, about 20 yards away, and by the 16th of January, 1926, a large number of persons using this system (the wealthier class) had contracted the disease Colon had from 150 to 200 cases of typhoid fever, and it was then that official reports began to be made of a few cases.

Suspecting the gravity of the situation, Doctor Rensoli, secretary of the department of health, sent experts to the scene and on receiving their telegraphic reports went to Colon himself, where he ordered the following measures to be taken: Chlorination of all water supplies; establishment of inoculation stations; painting and cleaning of meat shops and placing grates in their refrigerators; control of the

[1] Reported to the Academia de Ciencias Médicas, Físicas y Naturales de la Habana, by Dr José J. Chalons.

supply of milk, vegetables, etc , campaign against flies, and isolation of cases to avoid infection by direct contact.

The campaign against the epidemic was then actively undertaken by Doctor Chalons His first step on arrival in Colon was to hospitalize 60 or 70 cases existing among the destitute class of the city. The ice being found to be contaminated, the ice factory was ordered closed Similar measures were to have been taken with the soda-water plant, but its proprietor closed his place of business voluntarily.

The streets, theaters, and parks of Colon were deserted and commerce was at a standstill when the major operations of the campaign were undertaken

Chlorination of water —All water was treated with hypochlorite, and by the end of the incubation period an immediate effect was seen on the new-case incidence It is believed that this one measure reduced the force of the epidemic by at least 70 per cent

Contamination of water reduced —Pit latrines were immediately disconnected from the wells; the former were cleaned out and the latter thoroughly disinfected, the owners being warned that any further installation of a similar nature would render them liable to a fine of $500 in addition to criminal action.

Inoculation stations.—Four stations were established at convenient points, it being necessary to increase this number to five when the isolation of the town was completed.

Sanitary cordon.—With the aid of troops and police, a complete sanitary cordon was instituted, which prevented egress from the town to anyone not provided with an inoculation certificate and with a health certificate issued on the day of departure After the establishment of the cordon, no new cases were reported outside the town.

During the first few days on which the inoculation stations were in operation, only the persons conscious of the existing peril had recourse to them, at the rate of about 300 or 400 daily When this attendance decreased, inoculation was made compulsory, this measure bringing in about 1,700 persons the first day, about 1,300 the second and between 700 and 900 during the succeeding days, the number later falling off again. Knowing from the census that many of the inhabitants still remained unprotected, posters and circulars were distributed throughout the town by soldiers and police, announcing that all persons found uninoculated at the end of four days would be arrested and fined. This action induced from 800 to 1,000 people daily to come to the stations during the four days and inoculators were sent to the suburbs, in each of which about 300 people were inoculated.

At the end of the four-day period 200 of the inhabitants were apprehended and inoculated, this step bringing further applicants for protection, but in very reduced numbers, no doubt due to the fact that practically the whole population had been immunized. The 200 accused were given suspended sentences and the following day the sanitary cordon was discontinued.

In all, approximately 12,000 persons were immunized, and the epidemic was controlled. About 350 cases of the disease occurred.

PUBLIC HEALTH ENGINEERING ABSTRACTS

North Carolina Oysters. Anon. *Health Bulletin,* North Carolina State Board of Health, vol. 41, No. 2, February, 1926, pp. 3–8. (Abstract by R. E. Tarbett.)

The article covers the subject of North Carolina oysters and the method of carrying on sanitary control as it has been exercised during the past year.

The State board of health, in conjunction with the fisheries commission, has equipped a laboratory boat with which studies have been made of the shellfish-growing areas of North Carolina. In order to pay for this inspection, the oyster tax was increased 1¼ cents per bushel

A considerable percentage of the oysters taken from North Carolina waters are exported in the shell and taken by "buy" boats directly from the gatherers The tax is collected from these "buy" boats, and the inspector, at time of collection of the tax, issues a certificate of origin of the oysters to the captain of the boat. All these boats, in leaving North Carolina waters, must pass through a canal, and they are again boarded by an inspector to see that the captain has the certificate of origin as well as his tax receipt.

The amount of oysters dredged from North Carolina waters in 1926, was over 301,000 bushels. Practically this entire crop was disposed of under foreign label.

Work was also carried on relative to the sanitation of shucking plants.

The Influence of Hydrogen Ion Concentration on the Dose of Alum and the Mechanism of the Action of Alum in the Clarification of Natural Waters. N. L. Banerji (*Indian Jour. Med Research,* 11 (1924), No 3, pp. 695–718). From *Experiment Station Record,* U. S. Department of Agriculture, vol. 54, No. 4, March, 1926, p. 383. (Abstract by Arthur P. Miller)

"Studies are conducted which showed that, with other factors, such as suspended matter, size of particles, and concentration of electrolytes remaining constant, the optimum dose of alum for water

clarification increases and decreases with the pH, and that total hardness is an important factor in regulating the dose

"The mechanism of the action of aluminum sulphate is divided into two parts, due to unhydrolyzed aluminum sulphate and hydrolyzed aluminum sulphate. The positive aluminum ion from the unhydrolyzed portion is the most potent factor in clarification. The dose of alum can be decreased by the preliminary addition of sulphuric acid This is considered to be very important from the standpoint of economy in water clarification in the case of slow sand filters when the suspended matter in river water is very high"

Some Further Observations on the Species Method of Differentiating Fecal Organisms in Surface Waters in the Tropics. A D. Stewart and V G. Raju (*Indian Jour Med Research*, 11 (1924), No 4, pp 1157–1162) From *Experiment Station Record*, U S Department of Agriculture, vol 54, No 4, March, 1926, p 383 (Abstract by Arthur P Miller.)

"Studies are reported which showed that *B coli communis* is a very common organism in human feces, forming 29 per cent of the fecal organisms present and 26 per cent of those in septic tank latrine effluents It is distinctly rarer in cow manure, and forms only 12 per cent of the fecal bacilli. *B coli communis* is much rarer in waters which have received some natural purification, but is present in all waters subject to typical fecal pollution

"The numbers of *B coli communis* isolated from stored water were in marked contrast to those obtained from human feces, in spite of the fact that several of the samples examined had only a short period of storage *B. coli communis* formed only 8 per cent as against 29 per cent in human feces, 26 per cent in septic tank latrine effluents, and 20 per cent in typically polluted river water. *B neapolitanus* formed 37 per cent as against 32 per cent in crude human feces and 28 per cent in latrine effluents This is taken to indicate that this organism is not adversely affected by storage, and, consequently, the number found in stored waters is equal to or greater than that found in freshly polluted waters or crude human feces

"*B. coli communis* was not found at all in any of the waters subjected to prolonged storage, in spite of the fact that it was a predominating organism at the start. *B coscoroba* formed only 3 per cent of the organisms isolated from human feces, whereas in the case of cow manure it formed 20 per cent.

"The results of the examination of septic tank latrine effluents showed a close parallelism to those of human feces in important respects. These results are taken to indicate that the numerical proportion of the main fecal organisms is not materially altered in the course of the passage of the effluents through a septic tank. The storage and natural purification of polluted waters, on the other hand, caused certain important changes to take place in the fecal

flora and tended to alter the relative proportion of the different varieties originally present"

Analytical Study of the Waters of Antietam Creek. T. C. Schaetzle, sr, Asst San Engr, *Engineering Bulletin,* Maryland State Department of Health, vol 1, No. 2, September, 1925, pp. 105–141. (Abstract by T C. Schaetzle)

This article is concerned with a study of the waters of Antietam Creek, between Bridgeport and Funkstown, Md., for the period from September 11, 1923, to August 27, 1924. The investigation was made to determine the degree of pollution of this stream, with special reference to the relation of the biological growths in the stream to the chemical changes taking place therein.

At the time this investigation was begun the city of Hagerstown, with a population of approximately 30,000, was discharging its untreated sewage into Marsh Run, a tributary of Antietam Creek, located between Bridgeport and Funkstown During the period of investigation a Dorrco screen, a part of the sewage treatment plant, was placed in service. The screened sewage discharged into Antietam Creek below Marsh Run

A chemical, bacteriological, and microscopical study of the water from seven stations was made under various weather conditions. The analytical determinations include turbidity, color, suspended solids, total nitrogen, free and albuminoid ammonias, nitrites, nitrates, free carbon dioxide, dissolved oxygen, pH values, total and colon bacteria, and microscopic organisms. In the latter class, diatomaceæ predominated at all stations.

In addition to the tables and charts presented, the following conclusions were drawn: (1) The admission of sewage, whether treated or not, at two distinct points complicates the study of the self-purification of the stream; (2) the stream has not returned fully to its normal condition 2 miles below the sewage works discharge; (3) the discharge of screened sewage instead of raw sewage did not change materially the physical appearance of the stream a few hundred feet below the point of sewage discharge; (4) the entrance of organic matter into the stream increases the plant and animal life, (5) conditions on the bottom of the stream, with reference to the microscopic organisms, are of the same general nature as those existing in water, (6) the relation between the numbers of bacteria, algae, protozoa, and rotifera present in the waters of Antietam Creek and the organic pollution of the stream is established, but it is not conclusive enough to be of obvious diagnostic value; (7) the bacterial counts and some of the chemical constituents show clearly the pollution and dilution effects of Antietam Creek, with the subsequent self-purification of the stream; (8) the same general variations in the characteristics of the creek, due to seasonal changes and rainfall, occur above as well as below the points of sewage pollution.

COURT DECISIONS RELATING TO PUBLIC HEALTH

Increase in sum allowed by parish police jury for health work compelled.—(Louisiana Supreme Court; State ex rel Parish Board of Health of Calcasieu Parish *v.* Police Jury of Calcasieu Parish, 108 So. 104; decided March 29, 1926.) The board of health of Calcasieu Parish brought a mandamus proceeding to compel the police jury of the parish to budget and appropriate the sum of $5,251 for the operation and support of the board of health during the year 1926. Said sum was the estimate of expenses adopted by the board of health, but the police jury had placed in the budget the sum of $1,000. The police jury contended that it was the final arbiter in such matters in case of disagreement, but the supreme court held that under Act 79 of 1921 the board of health could by mandamus compel "proper action" by the police jury in the matter of budgeting, appropriating, or paying for "all necessary expenses, costs, and charges of local sanitation." The supreme court increased the amount of $1,000 allowed in the budget by the police jury to $3,600.

Payment of fees of local registrar of vital statistics.—(Missouri Supreme Court, State ex rel. Mitchell *v.* Rose et al., County Judges, 281 S. W. 396; decided March 15, 1926.) In a proceeding to compel the county court to pay to a local registrar of vital statistics the amount certified to the county court by the State registrar of vital statistics as due said local registrar, the supreme court held that, although the legislature had the power to provide for the payment of the fees to which a local registrar might be entitled out of the county treasury, it could not take away from the county court the right to call in question both the facts and the law on which the payment of such fees was demanded.

Payment of salary of purchasing agent for State detention home compelled.—(Colorado Supreme Court; Davis, State Auditor, *v.* Morley, 244 P. 599; decided March 8, 1926.) The purchasing agent for the State detention home, appointed by the State board of health pursuant to statutory authority, brought action for mandamus to compel the State auditor to issue warrants for his salary. The supreme court affirmed the judgment of the lower court awarding a writ of mandamus and held that the motive or intent of the State board of health in appointing the purchasing agent was irrelevant.

Additional tax for sanitary work held unlawful.—(California First District Court of Appeal; Spreckels *v* City and County of San Francisco, 244 P. 919; decided January 20, 1926.) One of the points decided in this case was that a tax, levied in the fiscal year 1910–11 by the city and county of San Francisco for the purpose of providing for the continuance of sanitary measures against bubonic plague, was for wholly preventive measures where cases of plague had not existed

in the municipality after 1907, and the situation was not one of "great necessity or emergency" within the meaning of the charter at that time warranting a temporary suspension of the limitation on the rate of taxation and the levy of an additional tax.

Enjoining of maternity hospital refused—(Texas Court of Civil Appeals; Perry et al. *v.* Ripley et al, 282 S W 329; decided February 13, 1926) Where a maternity hospital was conducted in conformity to law and there had been no abuse of discretion on the part of the local health officer in approving the application for license or on the part of the State board of health in granting the license, an injunction to restrain the operation of the hospital on the ground that the same might become a nuisance was refused by the court of civil appeals

Abattoir held to be a necessary municipal expense.—(North Carolina Supreme Court; Moore *v.* City of Greensboro, 132 S. E 565; decided April 14, 1926) The city council of Greensboro passed an ordinance providing for the sale of bonds for the purpose of buying a site and erecting thereon and equipping an abattoir; also the levy and collection of a tax annually for the payment of the interest and principal was provided for. The ordinance was not submitted to the voters of the city. In a suit to enjoin the city from issuing the bonds on the ground that an abattoir was not a necessary municipal expense, the supreme court held that it was a necessary expense within the meaning of section 7 of article 7 of the State constitution, and, therefore, the ordinance did not have to be submitted to the voters

Estoppel to complain of use of public incinerator.—(Kentucky Court of Appeals; Karcher *v.* City of Louisville, 281 S. W. 1010; decided March 26, 1926.) Where the plaintiff had negotiated the sale of an incinerator plant owned by his wife to the defendant city, knowing that the incinerator was to be employed by the city in the burning and destruction of garbage and dead animals, the court of appeals held that the plaintiff was estopped to complain of the city's use of the incinerator for the purpose for which it was intended.

DEATHS DURING WEEK ENDED JULY 24, 1926

Summary of information received by telegraph from industrial insurance companies for week ended July 24, 1926, and corresponding week of 1925. (From the Weekly Health Index, July 28, 1926, issued by the Bureau of the Census, Department of Commerce)

[4] Deaths for week ended Friday, July 23, 1926.
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31; Baltimore, 15; Birmingham, 39; Dallas, 15; Fort Worth, 14; Houston, 25; Kansas City, Kans., 14; Louisville, 17; Memphis, 38; Nashville, 30; New Orleans, 26; Norfolk, 38; Richmond, 32; and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

New York	3	1	2		1
Washington					1

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended July 17, 1926, 37 States reported 772 cases of diphtheria For the week ended July 18, 1925, the same States reported 772 cases of this disease One hundred and one cities, situated in all parts of the country and having an aggregate population of nearly 30,430,000, reported 547 cases of diphtheria for the week ended July 17, 1926 Last year for the corresponding week they reported 435 cases. The estimated expectancy for these cities was 613 cases The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-four States reported 3,565 cases of measles for the week ended July 17, 1926, and 1,414 cases of this disease for the week ended July 18, 1925 One hundred and one cities reported 1,254 cases of measles for the week this year and 880 cases last year.

Poliomyelitis.—The health officers of 37 States reported 53 cases of poliomyelitis for the week ended July 17, 1926. The same States reported 148 cases for the week ended July 18, 1925.

Scarlet fever —Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 1,130 cases; last year, 766 cases; 101 cities—this year, 545 cases; last year, 335 cases, estimated expectancy, 345 cases

Smallpox.—For the week ended July 17, 1926, 37 States reported 290 cases of smallpox Last year for the corresponding week they reported 260 cases One hundred and one cities reported smallpox for the week as follows: 1926, 41 cases; 1925, 82 cases; estimated expectancy, 61 cases One death from smallpox was reported by these cities for the week this year—at Omaha, Nebr

Typhoid fever.—Seven hundred and six cases of typhoid fever were reported for the week ended July 17, 1926, by 36 States. For the corresponding week of 1925, the same States reported 993 cases of this disease One hundred and one cities reported 126 cases of typhoid fever for the week this year and 208 cases for the corresponding week last year. The estimated expectancy for these cities was 155 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 95 cities, with a population of more than 29,700,000 as follows: 1926, 367 deaths; 1925, 317 deaths.

City reports for week ended July 17, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

The following table gives the rates per 100,000 population for 103 cities for the five-week period ended July 17, 1926, compared with those for a like period ended July 18, 1925 The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available The 103 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, June 13 to July 17, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

INCIDENCE OF ENDEMIC THYROID ENLARGEMENT IN CONNECTICUT

By ROBERT OLESEN, Surgeon, and NEIL E TAYLOR, Acting Assistant Surgeon, United States Public Health Service

INTRODUCTION

There is a widespread impression among professional as well as lay observers that endemic thyroid enlargement is relatively infrequent in Connecticut. This impression has been strengthened since the enunciation of the iodine deficiency theory of simple goiter causation. Connecticut lies wholly within the glaciated area and therefore a slight reduction in soil iodine may be expected. However, because of the proximity of the State to the seaboard and the excellence of the transportation facilities, by means of which iodine-containing foods are made available, it is improbable that there is a serious absolute deficiency of iodine. Consequently there is ample reason for assuming that endemic thyroid enlargement is comparatively infrequent in that State.

The principal information concerning goiter in Connecticut, and certainly that most widely quoted, was derived from the physical examinations of men drafted for military service during the World War.[1] In comparison with other States, Connecticut had relatively few instances either of simple or of exophthalmic goiter among the drafted men. However, it should be pointed out that the findings were based upon the recognition of 55 cases of exophthalmic goiter and 32 cases of simple goiter by a considerable number of examining physicians with varying degrees of skill and experience in diagnosis.

In view of the uncertainty as to the extent and distribution of endemic thyroid enlargement in Connecticut, the Public Health Service was requested by the State commissioner of health to undertake a thyroid survey. Consequently an investigation was made by the writers in the fall of 1925

1. HOW THE SURVEY WAS MADE

In cooperation with the Connecticut State Department of Health, to the officials of which the writers are greatly indebted for numerous courtesies and efficient cooperation, 28 representative communities

[1] Love, A G, and Davenport, C B Defects Found in Drafted Men Prepared under the direction of the Surgeon General, M W Ireland, War Department, Washington, D C Government Printing Office, 1920

were visited[2] In selecting these localities, indicated on Map 1, an effort was made to include the principal centers of population and different sections of the State If endemic thyroid enlargement should be more prevalent in one portion of the State than another it could be detected in such a State-wide survey.

Methods.—The thyroid examinations in Connecticut were limited to boys and girls in the high schools and upper grades of the grammar schools of the places visited In this way children of adolescent age, in whom endemic goiter may reasonably be expected to be present, were included in the investigation. The methods employed in making the examinations and the standards used in classifying the enlargements were identical with those applied in the Cincinnati and Colorado surveys.[3,4] Consequently the results are comparable

Scope of the survey.—In the 28 localities visited, the thyroids of 5,797 boys and 6,608 girls were examined. At the same time the condition of the tonsils and teeth were inspected for the purpose of determining a possible relationship between potential foci of infection and thyroid enlargement. The results of this latter study will be made the subject of a separate report. The method of supplementing a routine thyroid examination by collateral studies which may enhance our knowledge on the subject of goiter causation is recommended for more extended application Such collateral investigations require relatively little additional time and are usually enlightening.

2 THE RESULTS

In Table 1 are displayed the numbers, degrees, and percentages of thyroid enlargements occurring among 5,797 boys and 6,608 girls in the 28 localities studied. Among the boys there were 402 enlargements of all sizes, a percentage of 7. A greater number of enlargements, 1,945, or 29.4 per cent, were found among the girls.

The disproportion of thyroid enlargements between boys and girls included in the Connecticut survey is particularly noteworthy. Ordinarily endemic goiter is between two and one-half to six times more frequent among girls. For instance, the ratio of goiter prevalence among girls and boys in the Cincinnati survey was as 6 to 4, approximately 50 per cent of very slight thickenings being included in the estimate. In the Connecticut survey the proportion was 4.2 to 1.

---

[2] The writers are also under many obligations to the health officers, school physicians, school nurses, superintendents of schools, and teachers for assistance in making the examinations possible in the localities visited

[3] Olesen, Robert Thyroid Survey of 47,493 Elementary School Children in Cincinnati. Public Health Reports, vol 39, No 30, p 1778, July 25, 1924 (Reprint No 941)

[4] Olesen, Robert Endemic Goiter in Colorado Public Health Reports, vol. 40, No. 1, Jan. 2, 1925, pp 1-22 (Reprint No. 983.)

Marine [5] points out that the proportional incidence of goiter among the boys and girls of a given community may be used as an indicator in estimating the severity of the malady. Thus, in districts in which goiter is most severe in its manifestations, 100 per cent of both sexes have thyroid enlargement From this peak the condition gradually decreases in severity until the proportion becomes 10 to 1 in districts with sporadic occurrence of goiter.

Coming to a consideration of the degrees of thyroid enlargement among the boys it will be noted that there were 366 very slight and 35 slight enlargements, and only 1 moderate enlargement, percentages of 6 3, 0 6, and 0 017, respectively. Among the girls there were 1,428, or 21.6 per cent, very slight, and 426, or 6 4 per cent slight thyroid thickenings There were also 83, or 1.2 per cent, moderate, 6 marked, and 2 very marked thyroid involvements

Further differences between goiter prevalence in Cincinnati and Connecticut are apparent when degrees of enlargement are compared. In Cincinnati very slight enlargements prevail to about the same extent among girls and boys. Slight enlargements were twice as frequent among the girls Moderate thickenings were four times, marked thickenings six times, and very marked thickenings seven times more frequent among the Cincinnati girls.

An entirely different picture is presented when similar comparisons are made between goiter prevalence among girls and boys in Connecticut. Very slight involvements in Connecticut were four times and slight involvements twelve times more frequent among the girls. There were 91 moderate, marked, and very marked goiters among the girls and only 1 moderate goiter among the Connecticut boys It is evident from these comparisons that thyroid enlargement is proportionately and actually less frequent in Connecticut than in certain other sections of the country.

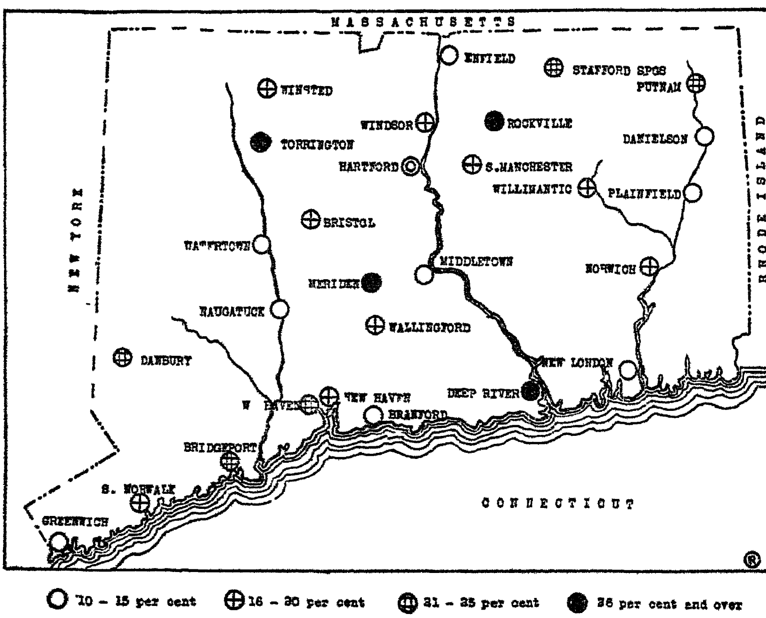
In addition to revealing the anticipated preponderance of thyroid enlargement among the girls the survey brought out other points of interest. Among the boys the enlargements were almost entirely of the very slight and slight varieties. Moreover, instead of the firm, tubelike, isthmial involvements so commonly encountered among boys in Cincinnati, the enlargements in Connecticut were more frequently of a diffused character Among the 98 boys examined in Plainfield there was no evidence of thyroid enlargement Other localities in which little involvement of the thyroid gland was detected among the boys were Naugatuck, Danielson, South Norwalk, and Watertown. Places with considerable thyroid involvement of slight degree among the boys were Meriden, Deep River, Middletown, and Willimantic.

[5] Dr David Marine, consultant in goiter studies, United States Public Health Service (Personal communication)

Among the girls, enlarged thyroids were noted most frequently in Torrington, Rockville, Deep River, and Meriden. The condition was least frequent among the girls in Hartford.

These variations are cited in order to indicate the irregularity of distribution of enlarged thyroids in the State Apparently geographical location, in so far as thyroid enlargement in this State is concerned, has little significance Localities along Long Island Sound, where thyroid enlargement should, theoretically at least, be comparatively infrequent, appear to have as much of the affection as do some of the places inland

Table 2 has been prepared for the purpose of showing the prevalence of thyroid enlargement in each sex separately, and both sexes



MAP 1—Showing percentage distribution of thyroid enlargement as disclosed by a survey of 5,797 boys and 6,608 girls in 28 localities in Connecticut

combined, in each of the 28 localities surveyed. This material is displayed graphically in Map 1 by means of symbols which denote varying percentages of prevalence. A total of 2,347 enlargements of all sizes, 18.9 per cent, were found among the 12,405 children examined. The least percentage of enlargement was found in Danielson, with 9.7 per cent, and the greatest percentage in Meriden, with 33.8 per cent. Between these extremes the percentages show no decided groupings or tendencies. In fact there is no single large section of the State in which endemic thyroid enlargement appears to be more prevalent than in another.

In Table 3 the numbers and degrees of thyroid enlargement are shown at each age period between 10 and 18 years. The tendency

for thyroid involvement to decrease as the ages of the boys increase is again well illustrated in this tabulation. Among the girls, on the other hand, endemic thyroid enlargement increases in frequency with succeeding age periods until the seventeenth year. These trends are graphically illustrated in Chart 1.

Comparison of data for Minnesota, Cincinnati, and Connecticut.—By comparing the results of the thyroid survey in Connecticut with similar data secured in other sections of the country a conception of the relative prevalence is possible. In a previous publication [6] it was possible to make such a comparison between the thyroid surveys in Minnesota and the city of Cincinnati Thus, among the children examined in 13 localities in Minnesota, 58 per cent had some degree of thyroid enlargement, in contrast to 33 per cent in Cincinnati. The frequency rate for girls in Minnesota was 71 per cent as compared with 40 per cent in Cincinnati Among the boys in Minnesota there were 41 per cent of enlargements while among the boys in Cincinnati there were 27 per cent of enlargements. In contrast to these figures the much lower rates of thyroid incidence in Connecticut may be cited, 7 per cent among the boys and 29 4 per cent among the girls The relative prevalence of thyroid enlargement among the boys and girls in Minnesota, Cincinnati, and Connecticut is clearly shown in Chart 1.

The age incidence of thyroid enlargements seems to be similar in all essential respects in the three sections of the country, though the rates are highest in Minnesota and lowest in Connecticut. The curve representing the combined moderate and marked enlargements of the Connecticut girls rises only slightly from the zero line, while the curve representing this data for the boys does not rise enough to be shown on this chart.

Asymmetry.—In the Cincinnati survey 7 9 per cent of the thyroid enlargements were found to be asymmetrical, the right-lobed thickenings being nine times more frequent than left-lobed involvements In the Connecticut survey, on the other hand, it was noted that asymmetry not only was less frequent but that left-lobed enlargements occurred just as frequently as did those involving the right lobe.

Relation of endemic goiter to drinking water.—The rôle played by drinking water in the causation of endemic goiter has been a subject for study and conjecture for many years. Various theories have been advanced for the purpose of proving that endemic thyroid enlargement is caused by one or another substance inherent to or lacking in the water consumed by a given population. Thus, the heavy impregnation of drinking water with lime salts, the presence

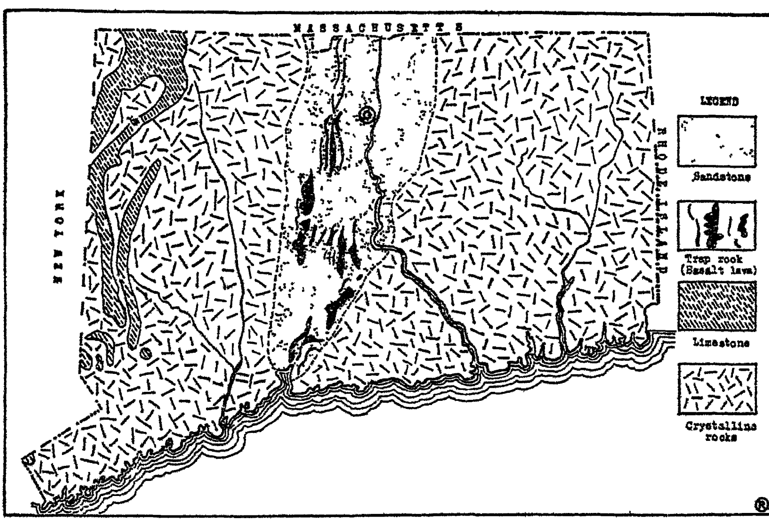
of unidentified microorganisms, the deficiency of iodine, and the absence of certain essential mineral salts have each been alleged to play a prominent part in goiter causation.

More recently the somewhat disturbing theory has been advanced that endemic goiter is due to the chlorination of drinking water. Moreover, the apparent increase in the amount of endemic thyroid enlargement has been ascribed to the increased use of chlorine in disinfecting water supplies

It has also been held that chlorine, by its disinfecting action upon water and the consequent destruction of microorganisms, is an active agent in preventing goiter. It is not the purpose, in the present article, to discuss the merits or defects of the several theories bearing upon this subject. However, such information as was obtained during the Connecticut survey will be presented.



MAP 2—Showing geologic formations in Connecticut

Unfortunately a State-wide series of determinations of iodine in drinking water is not available in Connecticut. However, judging from the results obtained in neighboring States, the iodine content of Connecticut drinking waters probably fluctuates considerably in various localities.

Sources and treatment of Connecticut water supplies—In Table 4 the source of the supply, the treatment, and whether or not chlorination is employed in the water supply of each of the 28 localities visited in Connecticut have been set forth. It will be noted that practically all the water available in these places is obtained from surface reservoirs. With a few exceptions, the supplies of water are subjected to storage for varying periods prior to use.

Geologic formations in Connecticut.—In view of the fact that goiter has long been held to be associated with certain geologic formations as, for instance, limestone, it is of interest to consider briefly the geology of Connecticut. The principal geologic formations, as shown in Map 2, are sandstone, trap rock (basalt lava), limestone and crystalline rock. The State may be divided, for geologic purposes, into three principal sections, the eastern and western highlands and the central lowland. All of the eastern and most of the western highlands are underlaid with crystalline rocks. In the western portion of the State there are also deposits of limestone. The central lowland is underlaid with sandstone and irregular outcroppings of trap rock. However, comparison of geologic formations and distributions of thyroid enlargements, as revealed by the surveys, fails to indicate a correlation.

SUMMARY

1. The thyroid survey in Connecticut included 5,797 boys and 6,608 girls in 28 localities.
2. In all, there were 2,347 thyroid enlargements, a percentage of 18.9, among the 12,405 children examined.
3. According to degree of thyroid enlargement there were 366, or 6.3 per cent, very slight enlargements among the boys, and 1,428, or 21.4 per cent, among the girls. There were 35, or 0.6 per cent, slight and only 1 moderate enlargement among the boys, while among the girls there were 426, or 6.4 per cent, slight and 63, or 1.2 per cent, moderate involvements. There were also 6 marked and 2 very marked enlargements among the girls.
4. Among the boys the percentages of thyroid involvement decline as the higher age periods are reached Among the girls, on the other hand, the percentages of enlargement increase until the age of 17 is reached.
5. In so far as the present survey is concerned there appears to be no section of the State of Connecticut in which endemic thyroid enlargement is more prevalent than another. However, the affection is more frequently encountered in some localities than in others.
6. A comparison of thyroid enlargement in Minnesota, Cincinnati, and Connecticut shows that the last named has the least amount.
7. There appears to be no correlation, in so far as the present study discloses, between the prevalence of thyroid enlargement and the principal geologic formations in Connecticut.

COMMENT

Endemic thyroid enlargement prevails to a far less extent in Connecticut than in certain other sections of the United States. Consequently two questions naturally arise in this connection:

1. Is the thyroid situation in Connecticut sufficiently important to require attention?

2 If the endemic thyroid problem is sufficiently important to merit consideration what action should be taken?

How much of a problem is goiter in Connecticut?—So long as endemic thyroid enlargement does not show a greater distribution than it does at present it would appear inexpedient and illogical for health officers and physicians to devote an undue share of attention to this single and comparatively minor phase of the general public-health problem Under the present circumstances the best general policy would appear to be one of conservative watchfulness.

However, two years hence, surveys should be made to determine whether an increase in the prevalence of endemic thyroid enlargement has taken place in the localities included in the present study. If such an increase has taken place widespread prophylactic and remedial efforts may be required On the other hand, should the affection appear stationary, intensive activity on the part of the State department of health, local health officers, physicians, and school authorities would probably not be indicated.

What should be done?[7]—At present the thyroid situation in Connecticut resolves itself into a consideration primarily of prevention and treatment of thyroid enlargement among adolescent girls The institution of State-wide goiter prophylaxis through the use of iodized water supplies, iodized table salt, or wholesale distribution of tablets containing iodine is not yet indicated in Connecticut. It is believed, however, that prophylactic measures should be carried out among girls between the ages of 11 and 16 years, under the direction of local health authorities, guided and assisted by the State department of health and the local medical practitioners. The prophylactic methods chosen appear to be immaterial, provided skilled supervision, low dosage of iodine, regularity and economy of administration are available.

Too often it is possible to secure a considerable per capita appropriation for goiter prophylaxis when it is difficult to obtain financial recognition of major public health projects. Goiter prevention should, of course, have a relative value, being alloted such a portion of the available funds as its comparative importance merits

There also appears to be a definite field in Connecticut for goiter prevention during pregnancy, thereby affording protection both to

[7] Commenting upon the suggestions made to the commissioner of health for meeting the conditions revealed during the present thyroid survey in Connecticut, Dr David Marine (personal communication) says "I can agree with every statement that has been made, particularly that of strongly recommending against the use of general prophylaxis under public supervision" Regarding the same subject, Dr H S. Plummer, consultant in goiter studies, United States Public Health Service, says (in a personal communication) "I approve of the concentrative stand taken in advising the Connecticut health authorities I am of the opinion that more intensive programs for goiter prevention should at present be concentrated where the disease is more prevalent."

the prospective mother and to the child. This prophylactic endeavor obviously depends upon the guidance of the medical profession and an educated public opinion.

Inasmuch as a considerable number of thyroid enlargements were detected among the girls examined, it is regarded as advisable that these children be placed under appropriate treatment. It should be pointed out that proper treatment consists of accurate diagnosis by a physician of skill, experience, and judgment, and the administration of appropriate remedies in minute doses, as well as nominal but regular supervision.

Marine[8] emphasizes the necessity for making an accurate distinction between goiter due to absolute and relative iodine deficiency. The former, of course, depends largely upon the lack of iodine in soil and water, whereas the latter is due to such factors as abnormal food, various types of infection, puberty, and pregnancy. Thyroid enlargements resulting from relative insufficiency of iodine must be handled as individual cases by competent physicians

Safeguarding iodine prophylaxis and treatment —Iodine in the form of Lugol's solution (compound solution of iodine) has been advocated as a temporary therapeutic measure in the treatment of exophthalmic goiter, in order that a patient may be brought into a satisfactory condition for operation.[8] Since this procedure has been advised, Lugol's solution has been used in the treatment of thyroid affections in which such medication has plainly been contraindicated. Consequently there have been numerous untoward and even disastrous results, causing widespread but unjustifiable condemnation of iodine as an agent in the prevention or treatment of all forms of goiter.

In view of the recently reported ill effects following iodine prophylaxis and treatment, it behooves those engaged in antigoiter activities not only to prescribe iodine in appropriately minute quantities, but also to be certain that iodine actually is indicated. It is just as important to know when to withhold iodine as when to administer it. Therefore, unless skilled treatment is available, it had best be withheld. Obviously, skillful treatment of thyroid conditions falls within the province of the especially qualified rather than the general medical practitioner.

[8] Regarding the use of iodine, Plummer says (personal communication). "The danger of giving iodine to adult patients having adenomatous goiter should be stressed. We have no reason to think that Lugol's solution is ever detrimental in cases having exophthalmic goiter Lugol's solution always benefits patients when that part of the complex which characterizes the disease is present, namely, the peculiar nervous phenomena and the stare "

CURRENT WORLD PREVALENCE OF DISEASE

REVIEW OF THE MONTHLY EPIDEMIOLOGICAL REPORT ISSUED MAY 15, 1926, BY THE HEALTH SECTION OF THE LEAGUE OF NATIONS' SECRETARIAT [1]

Mild outbreaks of influenza during March and April in a number of European cities are indicated by the data made available in the Epidemiological Report published May 15 by the health section of the League of Nations' Secretariat. A definite rise in the number of influenza deaths was reported for the German cities as a group, for Stockholm, Amsterdam, Paris, and Milan, but the effect on the general mortality in these localities was slight. Somewhat more severe was the increase in deaths from influenza in the 105 great towns of England and Wales, which reached a peak in the week ended April 17; but even here the effect on the general mortality was not great and the epidemic was of shorter duration than the epidemics of the preceding years.

The mortality from influenza in cities in eastern and central Europe, including Prague, Vienna, and Budapest, showed only a slight seasonal increase coincident with the outbreaks in western Europe.

[1] From the Office of Statistical Investigations, United States Public Health Service

Plague.—Very few cases of plague were reported from the Mediterranean area during April. Only 9 cases occurred in Egypt during the month, 1 of which was at Alexandria and 4 were at Suez. One case was reported at Piræus, Greece, on April 23.

At Baghdad, plague reappeared early in 1926, after having been quiescent during the year 1925, and the number of cases has gradually increased. There were 12 cases reported in the two weeks ended April 10, and 37 cases in the following two weeks Only sporadic cases have appeared elsewhere in Iraq, and Basra has remained free from infection

In India, 32,593 deaths from plague were reported in the four weeks ended April 10, an increase of approximately 50 per cent over the preceding four weeks, and also an excess of 50 per cent over the corresponding period of 1925 One-half of the deaths occurred in the Punjab, where plague is much more prevalent than it was a year ago, though considerably less so than two years ago. (See Fig. 1.)

DEATHS FROM PLAGUE IN THE PUNJAB, 1923-24, 1924-25 AND 1925-26

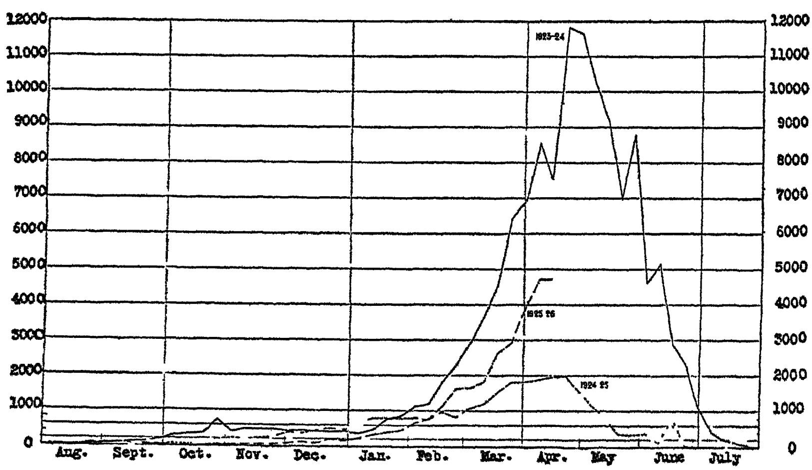

FIG 1

Plague was less prevalent during the early part of the year in Java, Siam, and French Indo-China than during the corresponding period of 1925.

The plague outbreak in the Orange Free State and adjacent districts of Cape Colony, Union of South Africa, resulted in 33 cases during March and April. Only four new cases were reported in the two weeks ended May 8.

Peru reported 394 cases of plague during the first quarter of 1926. All departments along the coast reported cases, except the northernmost and southernmost departments, but "the disease has never occurred in the Andes area or the provinces beyond the mountains," says the report.

Cholera—Cholera incidence was on the increase during April in Siam, French Indo-China, and India

In Siam, cholera cases started to increase about the middle of February, after having been declining during the two months preceding. New cases for the country outside of Bangkok showed no increase in the four weeks ended April 17 over the preceding four weeks, but the reports for Bangkok during the four weeks ended May 17 showed a marked increase in the upward trend of cases in that city.

TABLE 1.—*Cholera cases and deaths reported in Siam, September, 1925–April, 1926*

Four weeks ended—	Bangkok		Remainder of Siam	
	Cases	Deaths	Cases	Deaths
Sept 5	1	1	0	0
Oct 3	0	0	7	4
Oct 31	30	21	32	10
Nov 28	193	131	946	599
Dec 26	270	157	1,350	896
Jan 23	115	83	665	458
Feb 20	98	59	362	256
Mar 20	270	194	1,139	783
Apr 17	375	234	880	665
May 15	829			

In India more than half of the 8,211 deaths from cholera in the four weeks ended April 10 occurred in Bengal, and most of the remainder of the cases occurred in Bihar and Orissa and Madras Pres dency. While only 453 deaths from cholera were reported in Burma, this was a striking increase over the 76 deaths during the preceding four weeks and the 57 deaths in the corresponding four weeks of 1925. In French Indo-China, 2,469 cholera cases were reported during April, as compared with 1,666 in March. Approximately half of the cases were in Cambodia and half in Cochin-China, with a few in Laos.

Typhus and relapsing fever.—Typhus fever was somewhat more prevalent in Czechoslovakia during the winter 1925–26 than during the preceding winter; 286 cases were reported from November 1925 to April 1926, all in the sub-Carpathian part of the country, as compared with 60 cases during the corresponding six months of 1924–25

Both Bulgaria and the Kingdom of the Serbs, Croats, and Slovenes had a somewhat higher incidence of typhus fever in the first quarter of the year than in corresponding months of 1925.

Typhus fever was less prevalent in Poland and in Russia during the past winter than during any year since the World War. A few Russian districts bordering on the Ukraine did not show this decline.

Very few cases of relapsing fever were reported in recent months in Europe outside of Russia. In Russia the disease showed less decline than typhus as compared with 1925.

TABLE 2.—*Typhus and relapsing fever cases reported in European Russia (excluding the Ukraine) during the first two months of 1925 and 1926*

Geographical area	Typhus		Relapsing fever

Total	15,188	7,355	2,762	2,270

[1] Incomplete data

Korea reported 585 cases of typhus fever during the first quarter of the current year, nearly all in the Province of Keiko The disease is rare in Japan, and only 24 cases were reported in the first four months of 1926, 22 of which were in the district of Yamagata

The Epidemiological Report makes the following comment on relapsing fever in Africa:

Relapsing fever has been less prevalent during the early months of 1926 in the countries south of the north African Desert belt than during the corresponding season of the previous year. In Nigeria only 4 deaths from this disease were reported during the first quarter of the year, as against 202 during the first quarter of 1925 Only local outbreaks occurred at widely separated points of the Chad Colony and the upper Volta, being rather remnants of the terrible epidemics which visited these colonies during the previous years than in the nature of new epidemics. One hundred and two cases, 34 fatal, were reported during December in the subdistrict of Tougan, in the upper Volta, showing that the exceptional virulence of the disease nevertheless persisted. Two cases which occurred in Tunisia were the only relapsing fever cases reported during the first four months of the year in the African countries of the Mediterranean littoral

Smallpox.—Smallpox continued to be rare in most European countries. The situation in Switzerland has improved greatly in recent months and only five cases were reported in the 12 weeks ended May 12. The outbreak in northern England declined during April and May, with 662 cases reported in England and Wales during the four weeks ended May 22, approximately the same number that occurred in the corresponding period of 1925

Russia was unusually free from smallpox during the past winter; only the middle Volga area and districts further east reported more than a few sporadic cases.

"In North Africa the situation has been less favorable," says the report. "During the six months ending April 30, 1926, 1,608 cases were reported in Algeria, as against 766 and 62 cases, respectively, during the corresponding periods of 1924–25 and 1923–24. A similar, though less marked, increase has taken place in Egypt."

An outbreak of smallpox in the Gold Coast Colony was reported, with 601 cases during March. The type of disease appears to have been unusually mild, as very few deaths were reported. The Union of South Africa and British colonies and protectorates in South and East Africa were nearly free from smallpox in the first quarter of 1926.

Nearly half of the total cases of smallpox reported in India during March occurred in the Orissa division, where smallpox has been unusually prevalent. The annual maximum for this disease appears to have been reached in March.

Enteric fever.—April reports showed no change in the incidence of enteric fever in the various countries. Seasonal increases rarely occur in countries of the Northern Hemisphere before June. In Japan, where enteric fever was unusually prevalent early in the year, the April reports indicate a marked decline in the incidence of the disease, 1,480 cases having been reported during the four weeks ended April 24 as compared with 2,041 during the previous four weeks.

A rather wide variation in the fatality of enteric fever is shown by the data in Table 3. The report states: "It is probable that some of the high rates shown for certain countries in the table below may be due to incomplete case registration, but the disease is undoubtedly of a more severe type in certain non-European countries than in Europe."

TABLE 3.—*Fatality of enteric fever in certain countries during 1925*

Country	Cases	Deaths	Per cent fatal	Country	Cases	Deaths	Per cent fatal
Austria	718	52	7.2	Scotland (13 cities)	236	24	10.2

FIG. 2

Scarlet fever and diphtheria—The incidence of both scarlet fever and diphtheria showed a seasonal decline during March and April in the countries of the Northern Hemisphere The decline in the diphtheria incidence was less marked, however, than that in the scarlet fever incidence.

The reported cases of both scarlet fever and diphtheria in 11 European countries and in Japan are shown in Figure 2 by months or by four-week periods during the 16 months from January, 1925, to April, 1926 These graphs show quite clearly that scarlet fever was much more prevalent than diphtheria during this 16-month period. The diphtheria cases exceeded the scarlet fever cases only in France and Denmark, while the difference between them was slight in Germany and Italy In eastern Europe the scarlet fever cases outnumbered the diphtheria cases four or five to one It is clear from the graphs, also, that the seasonal variation in scarlet fever was greater than that for diphtheria.

CITY HEALTH OFFICERS, 1926

Directory of Those in Cities of 10,000 or More Population

Directories of the city health officers in the cities of the United States having a population of 10,000 or more have been published in the Public Health Reports [1] for each year from 1916 to 1925, for the information of health officers and others interested in public-health activities. These directories have been complied from data furnished by the health officers The cities included in this directory are those having 10,000 population or more on July 1, 1925, as estimated by the Bureau of the Census.

The asterisk (*) indicates that the officer so designated has been reported to be a "whole-time" health officer. For this purpose a "whole-time" officer is defined as "one who does not engage in the practice of medicine or any other business, but devotes all his time to official duties"

City	Name of health officer	Official title

TREATMENT OF INFANTILE PARALYSIS BY THE USE OF IMMUNE SERUM

The weekly Bulletin of the Department of Health of the City of Syracuse, N. Y, for July 24, 1926, gives an account of the appearance of nine cases of infantile paralysis during the month of July, 1926. The following is taken from the report of the treatment of this disease as given in the Bulletin

As soon as reports of the disease began to come in, arrangements were made for the usual diagnostic service. No immune serum was available at the time, but a small supply was immediately obtained through the courtesy of the State health department laboratories so that no case so far has suffered because of lack of serum An appeal was also made to the victims of this disease in the last two outbreaks—1924 and 1922—to give some of their immune serum blood Nurses of the department were sent to interview them personally As a result, a quantity of serum has been obtained and is now available It is hoped that further supplies may be obtained as needed.

ACUTE STAGE SYMPTOMS

It can not be overemphasized that parents and physicians must be on the lookout for the early symptoms of the disease. The onset is very much like that of any other infection A child previously well develops fever, headache, constipation, and vomiting Within some hours there may be some nervous irritability, tremor sweating about the face, retention of urine, stiffness and pain in the neck region, and perhaps also pain and tenderness in the limbs. The patient has an anxious look, much like that of an animal at bay. The fever tends to continue for three or four days, and then paralysis of groups of muscles supervenes. Lumbar puncture in the early stages usually gives a clear or slightly opalescent fluid under increased pressure, with an increased cell count and a positive globulin test.

TREATMENT OF THE DISEASE

The most important phase of the treatment is rest from the very beginning. The only possible specific treatment in the early preparalytic stage is the use of human immune poliomyelitis serum. This is injected intraspinally in amounts depending upon the amount of spinal fluid withdrawn by lumbar puncture. The intraspinal injection should be followed preferably with intravenous or intramuscular injections of amounts varying from 40 to 80 cc. In the outbreak of 1924, 35 cases were given human immune serum in the early stages of the disease, and only 4 were frankly paralyzed, while 3 showed transient weakness This means that 4 out of 5 in this group escaped paralysis, where ordinarily only about one-half the cases are expected to escape paralysis

After paralysis has set in, the most important thing is to leave the paralyzed muscles alone until every vestige of tenderness has entirely disappeared. The limb should be kept warm and at rest. No manipulation and no rubbing should be resorted to It is very difficult at this time to get the anxious parents to realize that this sort of treatment is the best for the recovery of the paralyzed muscles. After all pain and tenderness are gone, then, and only then, can muscle training and other forms of manipulation be resorted to with safety. For this stage of the disease orthopedic advice will be available as in former years.

A CLINIC FOR WHOOPING COUGH

Dr. Herman G. Weiskotten, Commissioner of Health for the City of Syracuse, N. Y., announces the opening of a clinic for whooping cough, the object of which will be to study and treat cases of this disease.

Already a gratifying response is manifest and many cases are undergoing treatment Facilities for laboratory diagnosis are provided in order that the disease may be recognized early

For purposes of study, cases are divided into (1) contacts who have not yet developed whooping cough. These will be given a prophylactic dose of vaccine Three injections will be given at intervals of three or four days (2) The second group is composed of early cases with a cough but without the typical whoop or paroxysmal cough In these cases the history of exposure and the examination of blood or sputum cultures should help to make a positive diagnosis. (3) The final group is made up of cases in which the cough is typically paroxysmal and there is no doubt as to the diagnosis In these cases an effort will be made to determine whether the disease can be shortened or the suffering ameliorated.

The reporting of whooping cough is stated to be far from complete.

PATIENTS IN HOSPITALS FOR MENTAL DISEASES, APRIL, 1926

Reports for the month of April, 1926, from 98 institutions for the care of persons suffering from mental diseases, located in 27 States, have been received by the Public Health Service A summary of these reports is given in the table below

The increase in total number of patients on the books during the month was 0.28 per cent. The increase in the number of patients in hospitals was 0.18 per cent, and in the number of patients on parole, 1.5 per cent.

Institutions having an aggregate of 9,778 patients did not report any of their inmates on parole Omitting these institutions, 8.6 per cent of the total number of patients were on parole April 30, 1926.

Omitting two institutions which care for male patients exclusively (420 patients), 51 3 per cent of the patients were males and 48.7 per cent were females.

Seventy-nine per cent of the patients admitted during the month were reported as first admissions, 14 7 per cent as readmissions, and 6 per cent were transferred from other institutions. Ten admissions (0.3 per cent) were not accounted for.

Thirty and four-tenths per cent of the patients discharged were reported as recovered, 48.1 per cent as improved, 14.2 per cent as unimproved, 4 4 per cent as without psychosis, and 2 9 per cent as otherwise discharged or not accounted for

The figures showing the number of transfers are incomplete, as transfers were made to and from hospitals from which reports were not received. It is possible that some patients were recorded as

transferred who came from institutions which do not care for mentally diseased persons

During the month 1,266 patients died, including patients who were on parole at the time of death This was 0 9 per cent of the average number of patients.

Patients on books Apr 1, 1926	
In hospitals	125, 926
On parole or otherwise absent but still on books	10, 759
Total	136, 685
Admitted during month	
First admissions	2, 430
Readmissions	451
Transferred from other hospitals in same State	186
Not accounted for	10
Total admitted during month	3, 077
Total on books during month	139, 762
Discharged during month·	
As recovered	385
As improved	610
As unimproved	180
As without psychosis	56
Otherwise discharged	18
Not accounted for	19
Total discharged during month	1, 268
Transferred to other hospitals in same State	162
Died during month	1, 266
Total discharged, transferred, and died (month)	2, 696
Patients on books Apr 30, 1926	
In hospitals	126, 147
On parole or otherwise absent but still on books	10, 919
Total	137, 066
Males	70, 525
Females	66, 541

PUBLIC HEALTH ENGINEERING ABSTRACTS

Some Notes on Mice and Bubonic Plague in Australia. Dr. F McCallum, Quarantine Officer, Commonwealth Department of Health *Health*, of the Commonwealth of Australia, Vol. 3, No. 6, November, 1925, pp. 175–177. (Abstract by H. N Old.)

While the house mouse, *Mus musculus*, has been found, under laboratory conditions, to show a relatively high susceptibility to infection with *Bacillus pestis*, the rather limited investigations conducted to establish a possible relation of mouse to bubonic plague

have resulted negatively The writer, however, feels that, in view of the swarms of mice which spread widely across the countryside at recurrent periods and particularly following in the wake of the harvesting of a successful wheat crop, the relationship of the mouse to bubonic plague, and possibly to other diseases of man, merits further investigation

Reference is made to the findings of several research workers who have conducted investigations along the line of mouse transmission of plague.

Mosquito Species Control of Malaria. Samuel T. Darling. *American Journal of Tropical Medicine*, Vol. 6, No. 3, May, 1926, pp 167–179 (Abstract by William Ropes.)

A study of malaria incidence in the rice fields and fish ponds of Java is presented, the author having been called in consultation because of the severity of the malaria and because the rice culture was so necessary and widespread control seemed at least financially impracticable. Spleen examinations showed a malaria infection of from 75 to 100 per cent, even among adults, and the population was proportionally poor, wretched, and "in a deplorable condition from malarial anemia." A careful survey of the anopheline mosquitoes revealed the fact that the breeding of the most dangerous species was not so widespread as might have been supposed, occurring principally in neglected rice fields, disused fish ponds, and ditches choked by vegetation. New rules were made governing the cultivation of rice and the breeding of fish, and the ditches were cleaned by the authorities As a result of the decrease in malaria-carrying mosquitoes, malaria has decreased, mortality rates are lower, and "a considerable improvement has been brought about with regard to the prosperity of the population" In his summary, Doctor Darling observes: "Every malarial problem should be defined first by field studies, for the breeding areas may be small and relatively easy to control."

DEATHS DURING WEEK ENDED JULY 31, 1926

Summary of information received by telegraph from industrial insurance companies for week ended July 31, 1926, and corresponding week of 1925 (From the Weekly Health Index, August 4, 1926, issued by the Bureau of the Census, Department of Commerce)

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week

State	Cerebrospinal meningitis	Diphtheria	Influenza	Malaria	Measles	Pellagra	Poliomyelitis	Scarlet fever	Smallpox	Typhoid fever
June, 1926										
California	17	503	48	6	2,150	8	16	608	103	111
Colorado	0	64	9	3	257		1	100	10	27
Delaware		6		2	92		0	17	0	3
Hawaii Territory	1	13	22		35		0	0	0	12
Kansas	4	31	45	2	783	1	3	107	29	34

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended July 24, 1926, 36 States reported 833 cases of diphtheria. For the week ended July 25, 1925, the same States reported 720 cases of this disease Ninety-seven cities, situated in all parts of the country and having an aggregate population of more than 29,560,000, reported 518 cases of diphtheria for the week ended July 24, 1926. Last year for the corresponding week they reported 419 cases. The estimated expectancy for these cities was 557 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-three States reported 2,750 cases of measles for the week ended July 24, 1926, and 957 cases of this disease for the

week ended July 25, 1925. Ninety-seven cities reported 871 cases of measles for the week this year and 544 cases last year.

Poliomyelitis.—The health officers of 36 States reported 48 cases of poliomyelitis for the week ended July 24, 1926. The same States reported 179 cases for the week ended July 25, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-six States—this year, 1,071 cases; last year, 717 cases; 97 cities—this year, 469 cases; last year, 296 cases, estimated expectancy, 273 cases.

Smallpox.—For the week ended July 24, 1926, 36 States reported 221 cases of smallpox. Last year for the corresponding week they reported 215 cases. Ninety-seven cities reported smallpox for the week as follows: 1926, 33 cases; 1925, 58 cases; estimated expectancy 51 cases. No deaths from smallpox were reported by these cities for the week this year

Typhoid fever.—Seven hundred and two cases of typhoid fever were reported for the week ended July 24, 1926, by 35 States. For the corresponding week of 1925, the same States reported 989 cases of this disease Ninety-seven cities reported 103 cases of typhoid fever for the week this year and 187 cases for the corresponding week last year The estimated expectancy for these cities was 169 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 91 cities, with a population of more than 28,875,000, as follows: 1926, 312 deaths; 1925, 267 deaths.

City reports for week ended July 24, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy

The following table gives the rates per 100,000 population for 102 cities for the five-week period ended July 24, 1926, compared with those for a like period ended July 25, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 102 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, June 20 to July 24, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst. Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain. (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual request.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

THE INFLUENZA EPIDEMIC OF 1926

A Preliminary Note on Certain Epidemiological Indications[1]

The wave of influenza in the late winter and spring of 1926 in the United States was more than ordinarily severe when compared with the influenza outbreaks which have occurred since 1920. Measured by the excess of mortality over the corresponding period in 1925, which was not an "influenza year," the toll in lives exacted by the disease was by no means negligible In fact, were it not for the over-shadowing pandemic of 1918, which caused over 500,000 deaths in the United States alone, and the epidemic of 1920, which caused about 100,000 deaths in this country, the 1926 outbreak would have been regarded as a calamity.

TABLE 1 —*Comparison of weekly mortality rates per 1,000 population from all causes in large cities of the United States during the period December 27, 1925–May 29, 1926, with those for the corresponding period in 1924–25*

Mar 13	17.7	15.0	2.7				
Mar 20	18.4	15.0	3.4				
Mar 27	19.4	14.8	4.6				

The data are from the current Weekly Health Index, Bureau of the Census, U S Department of Commerce

It is too early to make an accurate appraisal of the damage done by this year's influenza wave, but if we compare the mortality curve for all causes in the large cities of the United States from December 27, 1925, through May 29, 1926 (1), with the same curve for the corresponding weeks in 1924 and 1925, a very marked divergence is

[1] From the Office of Statistical Investigations, United States Public Health Service

shown, as may be seen in Table 1 and Figure 1 (A). Subtracting the 1925 rates from the 1926 rates, we obtain a series of "excess" rates and a curve that at once suggests a definite epidemic condi-

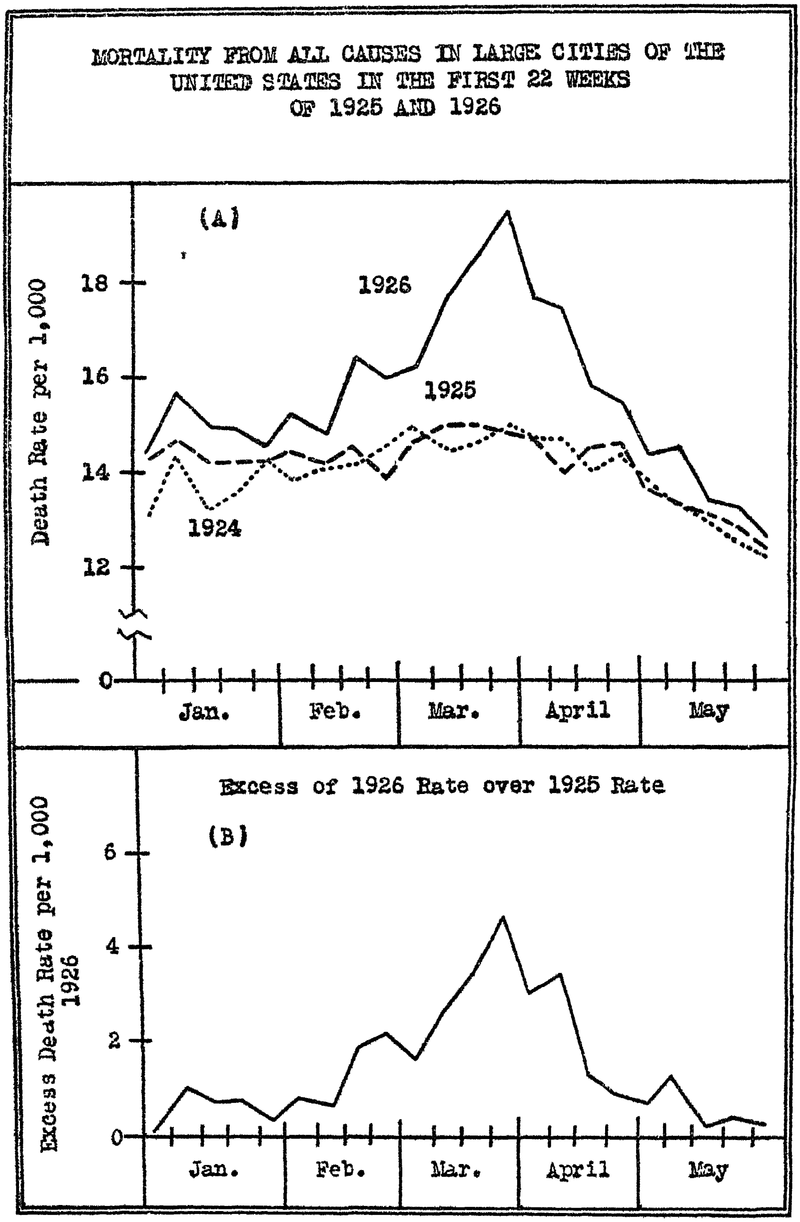

FIG 1

tion (Figure 1 (B)). The annual death rate in these cities rose to 19.4 per 1,000 in the week of March 21–27, which was 4.6 per 1,000, or 31 per cent higher than the rate for the corresponding week of

1925. Taking the period January 3 to April 30, 1926, and subtracting the deaths in the corresponding period of 1925, we obtain an excess of about 16,000 deaths in the 60-odd cities having a population of 100,000 or more and a gross population of about 30,000,000. Some of these deaths undoubtedly were due to the unusually high prevalence of measles, on the other hand, no allowance is made for any decrease in deaths from other causes or for deaths occurring after April 30 that are attributable to the epidemic. The excess death rate in these cities for the period in question was 0.53 per 1,000 and will probably add not less than that to the annual mortality rate which would have been expected for the year 1926 in this population. The mortality returns for towns and rural areas are not yet available, and it is unsafe to base an estimate of the increase in deaths for the entire country upon the experience of its larger cities, especially for an epidemic occurring in the spring

Some idea of how the 1926 epidemic fits into the picture of the "influenza waves" that have occurred since 1918–19 may be gained from the graph of weekly mortality from all causes in the same group of cities, as plotted in Figure 2 What may be termed a "normal seasonal" variation in the mortality rate has been eliminated roughly by a simple method [2] and the curve as plotted represents the remaining variations It is quite evident that there has been no marked upward or downward trend in the death rate during the seven years' period after the occurrence of certain deviations of a rather acute kind are taken into account. Certain variations of other types are indicated with which we are not concerned here. The maximal rates reached by the more acute deviations occurred in the weeks ending February 25, 1922, March 5, 1923, June 13, 1925, and March 27, 1926. The high mortality rate in June, 1925, undoubtedly was associated with the unusually sudden severe "heat wave" (2), the other four maximal rates were due in large measure to the increase in prevalence of respiratory diseases that commonly were diagnosed as "influenza," and were so recorded in reports of morbidity among various population groups for whom continuous records are available. In Figure 3 one record of this kind is shown graphically, which brings out the fact that in this particular group of persons in Boston, "influenza" or "grippe" was prevalent in the winter of 1924–25 The attacks were not reflected in the pneumonia rate, however. This occurrence was observed in other localities also, and no marked increase in mortality was evident.

Judging from the European records which are now available, the familiar pandemicity of influenza was a characteristic of the 1926

[2] The weekly death rates for annual periods beginning with July 1, 1921, 1924, and 1925, were used to determine roughly a seasonal variation in mortality not greatly affected by influenza or other acute outbreaks The weekly values in terms of mortality rate were read from a curve drawn by inspection, and the differences were plotted in the diagram reproduced in Figure 2

outbreak In the group of 105 Great Towns of England and Wales, a very marked increase in influenza mortality appeared in March, reaching its peak in the week ending April 17 The weekly records of cases of pneumonia in England and Wales show a synchronous rise and fall An epidemic condition, more or less severe, was manifested during February, March, and April in Glasgow, Paris, Amsterdam, Stockholm, the 46 German cities as a group, and Milan (3).

Although the severity of the 1926 outbreak, as measured by the mortality rate, was small in comparison with the severity of the 1918 epidemic, or compared with that of the 1920 epidemic, the three epidemics were similar in certain broad epidemiological respects, and markedly dissimilar in certain other respects. In Table 2, a comparison is made of the weekly excess mortality rates from influenza and pneumonia during the three epidemics in the large cities of the United States These rates have been plotted on a logarithmic ordinate scale in Figure 4, and the curves suggest: (1) A similarity from the point of view of duration, all of the waves having begun and ended within a period of three months, (2) a similarity in the time required for the epidemics to reach their maximal mortality rates, (3) a similarity in the *rate* at which mortality rose and fell, although it is suggested that the time required for the 1926 epidemic to spread and reach its crest was somewhat longer than that for the 1918 and 1920 epidemics. In other words, aside from some apparent differences which should not be considered until more complete records are available, these three outbreaks spread over the entire country in comparatively short periods of approximately the same length, and within that period they were generally similar with respect to their course from the point of view of time

[1] Excess over corresponding week of median year of the period 1910-1916 in cities included in the Weekly Health Index of the Bureau of the Census Data from Public Health Reports, March 26, 1920 (35 748)

[2] Excess over corresponding week of 1925 in 95 cities included in the Public Health Reports of the Public Health Service.

The 1926 outbreak was similar to the epidemics of 1918 and 1920 in another respect, namely, that there was a fairly definite geographic direction in which the wave traveled and spread But here the spatial similarity ceases; in fact, each of these epidemic waves had its own particular direction. It will be recalled that in the autumn of 1918 the epidemic first manifested itself in New England

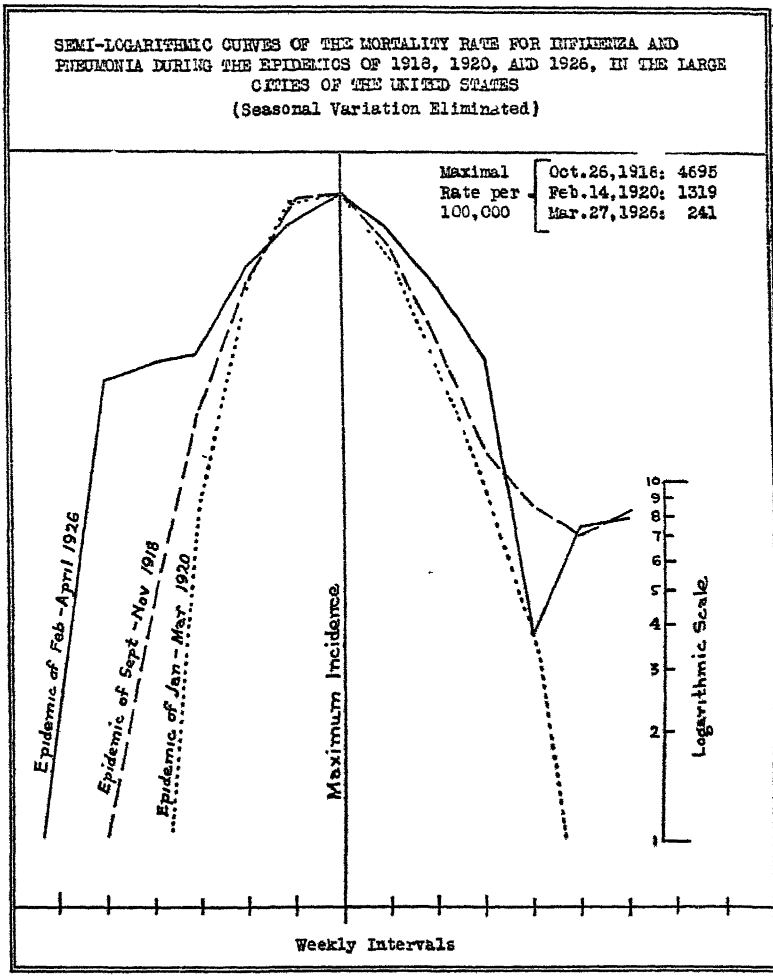

FIG. 4

and then spread south and west, first appearing in the larger cities in its course, and later radiating from these cities into the surrounding areas (4) The 1920 epidemic, on the other hand, appeared first in the North Central section and apparently spread to the East, South, and West, in somewhat the same manner as did its greater predecessor (5). Certain localities appeared as exceptions in either

epidemic, but the general directions were fairly clear. The 1926 epidemic, however, seems to have traveled in directions entirely different from those of either of the two preceding epidemics; apparently the main general direction was from the west and southwest to the southeast and then north, the New England section being the latest affected

The geographic course of the epidemic can be described more clearly by a graphic presentation of certain data now at hand In Figure 5 there are plotted the weekly number of cases reported by telegraph to the United States Public Health Service by the health departments of 16 States, selected for use here chiefly because of their geographic location and partly because of certain qualities of their reports[1] The States are arranged in the chronological order in which the peak in the cases reported occurred Thus, in California the influenza wave appeared earlier than in any other section represented The epidemic next appeared in the sections represented by Utah, by New Mexico, and by Oregon, omitting Maryland for the moment It apparently moved east, reaching the Southern States first, and the Northeastern States last. The geographic course of the outbreak is also indicated by the weekly reports to the Public Health Service from several hundred towns and cities. In 106 of these the influenza reports showed a fairly definite epidemic condition, namely, an increase and fall in the number of cases reported within a period of a few weeks The week in which the number of these cases reached its peak in each of these 106 larger towns and cities has been marked on the map which is reproduced in Figure 6 Unfortunately for our purpose, cities are relatively infrequent in the western section where the path of the epidemic would be especially interesting to follow But the broad directions seem to be fairly clear; again it is indicated that the earliest manifestations of the epidemic were on the middle Pacific coast, whence it spread southeast, and from the southern section north and east.

It is to be regarded as quite probable that, had we more definite information on many more localities, the picture might be quite different in its detail. In Figure 5 it was shown that the principal part of the epidemic in Maryland occurred in the latter part of January and the early part of February The same indication is given in Figure 6 In Baltimore the greatest excess (over 1925) in the mortality rate occurred in the week ending February 13, and an increased death rate had manifested itself two or three weeks before In Richmond, Va., this maximum occurred only two weeks later. In Savannah, Brunswick, and Atlanta, Ga., the reports suggested the occurrence of a rise in influenza cases at about the same time as in Balti-

[1] The number of cases reported can not, of course, be taken as an indication of the actual incidence, but the reports are satisfactory for showing roughly the chronological behavior of the disease and for comparing different areas or localities with respect to this point

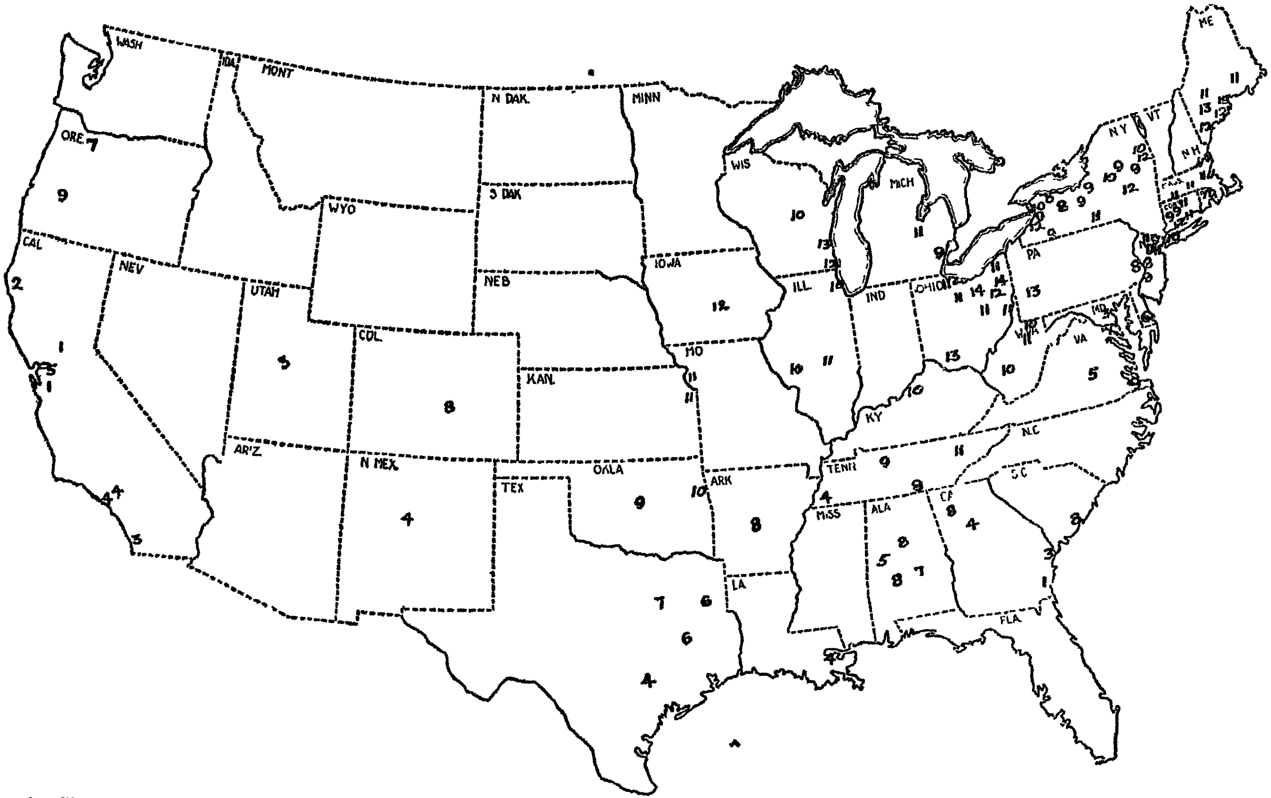

FIG. 6.—Chronological order, by weeks, of maximum incidence of cases of influenza reported in each of 106 cities in the United States, January 10–May 1, 1926. Week ended January 16=1, week ended January 13=2, week ended May 1=15

more. Thus, at certain points at least on or near the south Atlantic seaboard there were evidences of unusual influenza prevalence at about the same time or within two or three weeks of its appearance in the middle Pacific coast region

The weekly excess death rates from influenza and pneumonia in the 96 cities, as shown in Figure 7, give some idea of the relative severity of the epidemic in the principal cities in different sections of the United States, as well as of the direction of its spread It appears that in the West North Central section the usual seasonal mortality was hardly affected at all, and the epidemic did not manifest itself in a sharp or severe form. On the other hand, its effects were much more marked and severe in the other sections, particularly in the cities in the Middle Atlantic States A great variation in mortality from epidemic influenza, it will be recalled, was manifested among different cities in 1918–19 and 1920, a variation that Pearl (6) found to be correlated, so far as the 1918 pandemic was concerned, with the death rates from certain organic diseases in previous years The same sort of a variation undoubtedly appeared in 1926, whether or not it is associated with the mortality from other causes in nonepidemic periods or from influenza in prior epidemics can not be determined until the records are more complete. In fact, the studies conducted by the United States Public Health Service on morbidity from influenza in 1918 show quite definitely that the incidence rate for cases differed markedly in different localities and that there was an equally striking variation in case fatality (7), so that, lacking contrary evidence, we may assume that similar differences will account for the variations in the mortality rate in 1926. The mortality experience in European cities in 1926 is very much the same as that in American cities In Glasgow a rather severe epidemic occurred, whereas increased influenza mortality did not manifest itself at all in Dublin, and in Belfast a month or more later. In London, Paris, and several Italian cities, for example, quite definite indications are given by the current records of an increased mortality from influenza in the spring of 1926, whereas in Vienna, Prague, Budapest, and Swiss cities there is little or no evidence of such an increase (3).

The current disease reports issued by the Surgeon General's office, War Department (8), show quite definitely not only a rise in the incidence of influenza but also a concurrent increased incidence of secondary pneumonia among troops in the United States during the period January–May, 1926. This is not reflected to any considerable extent in the rates for "common respiratory" diseases or "primary pneumonia." The weekly rates on an annual basis are plotted as a series of graphs in Figure 8, with similar graphs for 1925 for comparison.

FIG 7

We are accustomed to examine first such indications as are afforded by the records of mortality according to age, chiefly, perhaps, for the reason that the 1918 pandemic presented an age fatality curve that was in striking contrast to that shown by nearly every other important disease. Unfortunately we shall have to wait until the mortality statistics are tabulated in greater detail before any comprehensive analysis of the 1926 data can be made, but the records for all causes

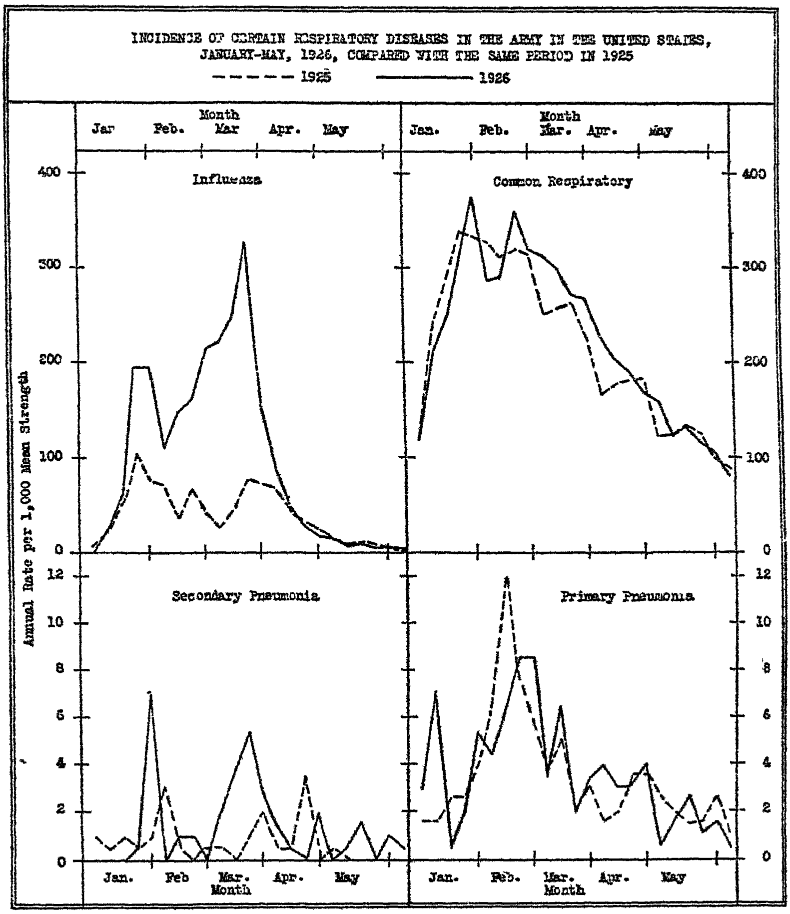

FIG. 8

now available in current reports for two large localities are not without interest. These are the widely separated cities of New York and New Orleans. Since it is important to eliminate as far as we can the deaths which ordinarily are expected to occur, we have simply subtracted the number of deaths reported for each age group in 1925 from those reported in 1926, only the epidemic period of 1926 and the corresponding calendar period of 1925 being considered.

TABLE 3.—*Increase in deaths at different ages in New York City during the period February 13–April 17, 1926, over the corresponding period in 1925*

Age (years)	Number of deaths		Per cent increase 1926 over 1925
	1925	Excess in 1926	
0–4	2,319	1,224	53
5–64	8,238	1,479	18
65	3,461	1,661	48

The result for New York City is given in Table 3 (9). The age grouping used by the New York City health department does not permit of much refinement, but the indication afforded seems to be clear enough so far as the data allow During the period February 13–April 17, 1926, when influenza mortality was abnormally high, there was an increase of about 50 per cent in deaths under 5 and over 64 years of age as against a very much smaller increase for the age 5–64. Somewhat more refined age groupings, as well as distinctions as to color and sex, are available for New Orleans (10). Here (Table 4) it is even more definitely shown that during the 1926 epidemic the increase in mortality was confined chiefly to the extremes of life—under 5 years, and 70 years and over—although some increase is evidenced in the age group 50–69 years The indication is shown for both whites and negroes.[4] Just how much of the increase in the death rate among young children was due to the widespread prevalence of measles can not be determined until further details are available with respect to cause of death at different ages, but it is probable that some of this increase may be accounted for in this way.

TABLE 4.—*Increase in deaths at different ages in New Orleans during January–February, 1926, over the corresponding period in 1925, by color*

Age (years)	Number of deaths				Per cent increase 1926 over 1925	
	1925		Excess in 1926			
	White	Colored	White	Colored	White	Colored
0–4	116	95	48	21	41	22
5–14	23	18	−3	3	−13	17
15–24	60	61	−25	−10	−42	−16
25–49	204	248	14	−6	7	2
50–69	281	131	80	55	28	42
70+	160	52	109	31	68	60

[4] The mortality by sex in New Orleans shows no difference in the excess for all causes, the increase over 1925 being 21 and 20 per cent for males and females, respectively The number of deaths from influenza among males in January–February, 1926, was 53, or 26 per cent higher than in 1925, whereas among females the number of influenza deaths was 57, or 96 per cent higher than in 1925 The numbers are too small, however, to afford any conclusive evidence.

If we consider the age curves for mortality from various respiratory diseases, the suggestion afforded by these fragmentary data on the age incidence of the increased mortality during the influenza epidemic is that the mortality was due, in greater degree than usual, to sequelae of broncho pneumonia. Tewksbury (11), commenting upon the Pennsylvania mortality reports for March, 1926, points out that "the 1918 and 1920 epidemics were chiefly influenzal in character, the influenza-pneumonia ratio being 2 0 and 1 3 to 1, respectively," but that "the 1923 and 1926 epidemics were. on the other hand, chiefly pneumonic in character. the influenza-pneumonia

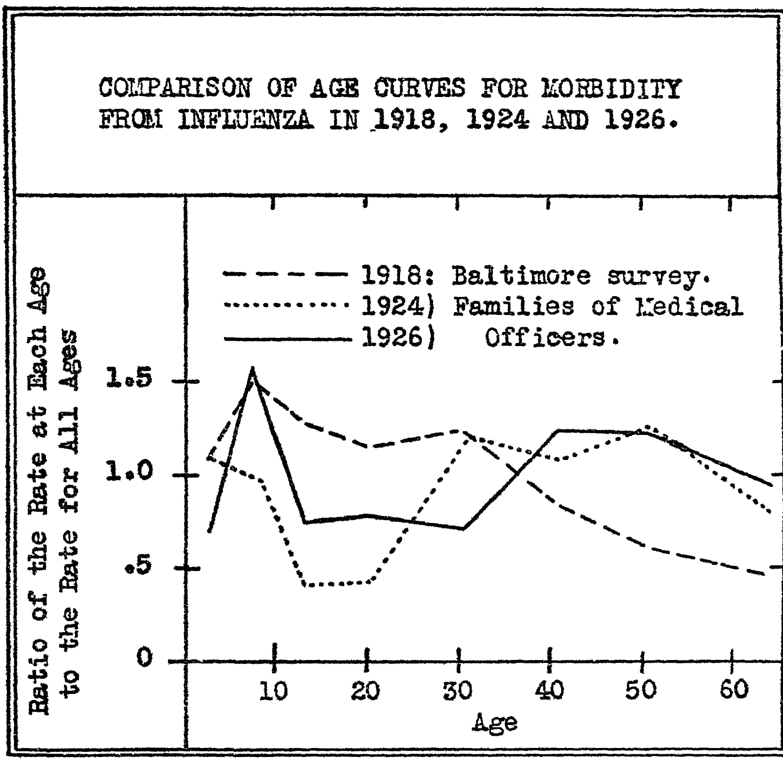

FIG. 9

ratio being 0.4 to 1 and 0 5 to 1, respectively" This observation is not a general one, however The Wisconsin health department comments to the effect that while the chief increase in the number of deaths from communicable diseases in the first quarter of 1926 was due to influenza, there was in the same period a decrease in the mortality from pneumonia, and draws the conclusion that "influenza deaths during the past three months were not complicated with pneumonia to the same extent as in some of the former epidemics" (12). It is regarded as quite probable that the severity of cases in this epidemic, as in former epidemics, varied geographically.

The influenza cases in families of medical officers of the Army, Navy, and Public Health Service, who are collaborating with the Office of Influenza Investigations of the Public Health Service, may also be used to indicate age incidence Expressing the incidence at different ages in a form of *relative* variation (i e, the ratio of the rate for each age to the rate for all ages) we have in Figure 9 compared the variations according to age of the 1926 influenza cases in the medical officers' families with those of influenza cases in 1918 recorded in Baltimore (13) in a large population group and with those occurring in 1924 in the same medical officers' families The 1918 cases were, of course, pandemic in character The 1924 cases did not occur during an epidemic and followed the usual seasonal course of common respiratory diseases It will be noted, with respect to the age curve for 1926, that a relatively high incidence is shown in the ages 5–9 and 35–54 The comparison between the curves for the three years suggests that the interepidemic (1924) influenza affected persons of the ages 10–24 far less (relatively) than the pandemic (1918) influenza, but also less than the kind of influenza we had in 1926 On the other hand, relatively speaking, the incidence of 1926 influenza cases was similar to that of 1918 in the age period 5–9, but was higher in the ages 35 years and over.

CURRENT WORLD PREVALENCE OF DISEASE

REVIEW OF THE MONTHLY EPIDEMIOLOGICAL REPORT ISSUED JUNE 15, 1926, BY THE HEALTH SECTION OF THE LEAGUE OF NATIONS' SECRETARIAT[1]

An influenza outbreak occurred in Northern Ireland during the latter part of April and reached its peak about the middle of May, according to information in the Epidemiological Report published June 15 by the health section of the League of Nations' secretariat. This was approximately one month later than the spring influenza outbreaks which occurred in Scotland and England. Reports from the Irish Free State did not indicate any coincident increase in influenza in that part of Ireland. The mortality from all causes and deaths from influenza in towns in Ireland, in Scotland, and in England and Wales during recent weeks are given in the accompanying table

TABLE 1.—*General mortality and deaths from influenza in British towns from March to May, 1926*

Two weeks ended—	105 English and Welsh towns		16 Scottish towns		7 towns in Northern Ireland	
	Mortality per 1,000 (all causes)	Number of deaths from influenza	Mortality per 1,000 (all causes)	Number of deaths from influenza	Mortality per 1,000 (all causes)	Number of deaths from influenza
Mar 13	12.7	185	15.0	27	14.5	0
Mar 27	13.4	272	17.2	43	16.3	2
Apr 10	15.1	517	21.7	196	15.9	3
Apr 24	13.7	511	19.0	138	19.8	6
May 8	12.1	315	15.5	52	19.6	22
May 22	11.7	229	14.1	32	21.1	50
June 5	10.9	158	13.4	12	18.5	32

In Denmark, 12,760 influenza cases were reported during May, as against 10,539 during April In 1925, April was the month of maximum prevalence of influenza in Denmark, while the maximum occurred in March in 1924 and 1923, and in January in 1922 In Sweden the number of influenza cases has declined since February. In the Netherlands a considerable increase in the number of deaths from influenza was reported for April as compared with March.

Plague.—The plague situation in the Mediterranean ports continued favorable during May There were two cases reported at Constantinople, two in Greece—one case at Zante and one at Patras—and eight cases reported at Suez in the six weeks ended June 12. A few cases were reported also from the inland Provinces of Egypt, mostly from Beni-Suef.

[1] From the Office of Statistical Investigations, U. S. Public Health Service

An outbreak of plague occurred in Tunisia at Kairwan, an inland district, and 122 cases were reported between May 11 and June 10. One case each was reported at Sfax, at Susa, and at Tangier.

"Plague was about twice as prevalent in India during April as during the corresponding month of the preceding year," states the Report. "This is entirely due to the high prevalence in the United Provinces and especially in the Punjab, where the curve of prevalence was intermediate between that of the relatively severe epidemic of 1924 and the low incidence of 1925 The Punjab epidemic appears to have reached its maximum during the week ended April 24, which is about the normal period for the plague maximum in this Province. More plague cases were reported in the United Provinces during April than during March—an event which has happened only once before, in the exceptionally severe outbreak of 1907. There were 9,103 deaths from plague in the United Provinces during the four weeks ended May 1, as against 6,949 during the preceding four weeks "

An outbreak of plague at Amoy began the first week in May, and in six weeks 49 cases were reported.

The number of plague cases in Iraq had increased up to the middle of May. At Baghdad 83 cases were reported in the two weeks ended May 22, as against 39 cases during the preceding two weeks. Cases also occurred in the neighboring districts, but Basra was still free from infection.

In Madagascar the number of cases of plague declined from 101 during April to 25 in May. In Kenya the number of cases dropped from 81 in March to 37 in April.

Cholera.—"The greater part of the Indo-Chinese Peninsula has become infected" says the Report, "the disease (cholera) having spread slowly from river to river and from port to port " In Siam, excluding Bangkok, 6,429 cases had been reported from the beginning of the outbreak last October up to May 8. During April the weekly number of cases was increasing, and 487 cases were reported in the last week in April, as against 339 in the preceding week. Up to June 12, 3,018 cases of cholera had been reported at Bangkok since last October; but the peak of the epidemic there seems to have been reached in the week ended May 22, when 362 cases were reported. In the succeeding three weeks, 219, 146, and 116 cases were reported, respectively.

In French Indo-China, 6,310 cases of cholera had been reported up to the end of May. The infection had spread to Haiphong, in Tonkin, at the end of May, and 103 cases were reported in the week ended June 12, the fourth week of the outbreak

The incidence of cholera in India increased rapidly from the middle of March to the middle of April, and then began to diminish somewhat. The cholera incidence has been particularly heavy in Bengal, where nearly one-half the total deaths from the disease occurred. Bihar also has been severely affected Deaths in the various Provinces are shown in Table 2.

TABLE 2 —*Cholera deaths reported in the Provinces of India*

Province	1926		1925	Province	1926		1925
	Mar 7–Apr 3	Apr 4–May 1	Apr 5–May 2		Mar 7–Apr 3	Apr 4–May 1	Apr 5–May 2

[1] Two weeks only.

Smallpox.—No change in the prevalence of smallpox on the European Continent during April or May was noted, the disease being rare or absent in most of the countries according to reports received. In England, the incidence increased somewhat during the second half of May, especially in the county of Durham. Cases reported during the four weeks ended June 12 numbered 776, compared with 630 in the preceding four weeks.

Smallpox continued prevalent in Algeria, where there were 183 cases during May, and 181 during April. In Egypt, 261 deaths from smallpox occurred in the first 15 weeks of 1926, as against 23 during the corresponding period of the preceding year.

Smallpox cases increased in Japan during the spring, and 785 cases were reported from January 1 to May 15, of which 516 were in the island of Kiushiu. There has been an increase also in Korea and in Kwangtung.

Cerebrospinal meningitis.—"The incidence of cerebrospinal meningitis in Europe has been much the same during the past winter and spring as during the corresponding period of the previous two years," states the Report. "One thousand six hundred and eighty-six cases were reported in 17 European countries during the first four or five months of 1926, as against 1,672 and 1,568 cases, respectively, during the corresponding periods of 1925 and 1924 in the same countries."

TABLE 3.—*Cerebrospinal meningitis cases reported in various countries during the first four or five months of 1924, 1925, and 1926*

New Zealand	16 weeks	11	11	11

Measles.—The incidence of measles was higher during the first four or five months of 1926 than during the corresponding period of 1925 in Scotland, Northern Ireland, the Netherlands, Denmark, Poland, and Switzerland, but lower in France, Italy, and the Balkans. The disease was three or four times as prevalent in the United States during the past spring as in 1925.

Malaria.—Malaria was somewhat less prevalent in Russia in 1925 than in either of the preceding two years The greatest continuous decline during these three years was in the northeastern area, the central industrial area, and the Middle Volga area. In the Ural district the disease was epidemic in 1924, but declined markedly in 1925, as was also the case in the Ukraine. On the other hand, more cases were reported in 1925 than in the previous two years in Turkestan, Kirghiz, the Caucasus, the Crimea, and in White Russia. The number of cases in each geographical area in each of the three years is given in Table 4.

TABLE 4.—*Malaria cases reported in the U. S. S. R. by geographical divisions, 1923–1925*

Geographical area	1923	1924	1925
North-Eastern	38,932	11,468	6,535

Trans-Caucasus	173,281	358,996	391,119
Kirghiz	171,032	202,167	224,008
Turkestan	80,563	68,744	133,727
Siberia and Far East	218,120	425,693	350,262
Railways and waterways	609,323	313,529	210,279
	5,556,856	5,983,477	5,124,719

The following comment on the seasonal distribution of malaria in these three years is taken from the Epidemiological Report:

The seasonal curve of malaria incidence showed during 1925 two distinct maxima, one in June and the other in August, while during the two preceding years the curve for the whole Union of Socialist Soviet Republics had only one maximum, which occurred at the end of May. In order to understand this change it must be recalled that the maximum of the benign tertian malaria usually occurs in May and of the malignant tropical forms in the autumn. The latter have been most prevalent in central Asia, the Caucasus, and the Volga area, while the former prevails in central-western and northern Russian and in the Ukraine. The decline of the malaria incidence in this part of the country and its increase in the southeastern area of the Union have brought the autumnal type more in evidence. The maximum incidence in the Ukraine occurred in May, 1925, as was the case in 1924.

TABLE 5.—*Percentage distribution, by months, of malaria cases reported in the U. S. S. R. during 1923 to 1925*

Month	1923	1924	1925	Month	1923	1924	1925
January	2.5	2.6	3.6	August	13.8	9.8	12.1
February	2.8	3.3	4.4	September	9.8	8.0	11.7
March	5.4	5.7	7.1	October	6.5	4.4	7.9
April	9.4	13.4	10.2	November	3.4	2.2	5.6
May	15.3	20.4	12.6	December	1.9	2.1	3.9
June	15.7	15.6	11.4				
July	13.5	12.5	9.5		100	100	100

The number of malaria cases has shown a steady decline in Poland during the past four years as follows: In 1921, 52,965 cases; in 1922, 17,611; in 1923, 4,770; in 1924, 1,881; and in 1925, 1,775 cases.

Trachoma.—Statistics on trachoma are reported regularly by only a few countries, and are rarely complete. Sudden increases in the diseases may signify only increased efforts in the campaign against it. Data from those countries reporting the disease currently are given in Table 6.

TABLE 6.—*Trachoma cases reported in various countries, 1924–1926*

THE RECENT TREND OF PUERPERAL MORTALITY [1]

During the past decade there has occurred a wide extension of nursing and of other measures directed toward the prevention of the serious and often fatal complications of the puerperal state. Public and private agencies have endeavored to provide instruction and supervision for pregnant women, increasingly stringent regulations of midwifery have been instituted, hospital service in confinement has been much improved and made widely available, and post-natal care has been provided through public health nursing agencies working in the home. It is of interest, therefore, to examine the Census Bureau's records of the mortality from abnormalities associated with childbearing for an area of the United States [2] where

[1] From the Statistical Bulletin, Metropolitan Life Insurance Co., July, 1926.
[2] Connecticut, District of Columbia, Maine, Massachusetts, Michigan, Minnesota, New Hampshire, New York, Pennsylvania, and Vermont.

much of the admitted improvement in maternity service has taken place during the past 10 years

There seems to have been a slight increase in the death rate for puerperal conditions reckoned against births in a constant area This is clear from a comparison of the rates for the two periods 1915–1917 and 1921–1923. The death rates for puerperal sepsis and puerperal eclampsia have remained unchanged These two conditions account for more than one-half of the mortality connected with childbearing. Most of the preventive effort of agencies for maternal care has been directed at these two conditions.

Some improvement in the mortality figures has been observed in rural districts of these nine States But here we have to consider the effect of improvement in birth registration An increase in the proportion of births registered would tend to decrease puerperal mortality rates based upon births

The fact that there has been no significant improvement in maternal mortality rates during the period under review should provoke inquiry What could have been expected of the maternity work which was instituted with such fervor and zeal ten years ago? Was it founded upon sound principles, were its aims realizable, and was there a program sufficiently comprehensive to affect the vast number of maternity cases which occur annually in the area under survey? Or, have new factors intervened to offset the work of boards of health and of private agencies? Has the increased proportion of hospitalized cases been accompanied by more septic complications? Whatever be the answers to these and other questions which arise, it is clear that over the past decade little if any impression seems to have been made upon the risk of death in childbearing.

INFANT MORTALITY IN LARGE CITIES OF THE BIRTH REGISTRATION AREA, 1926

The Department of Commerce has issued the following statement showing the number of deaths of infants under 1 year of age per 1,000 births for the white and colored populations in selected cities of the birth registration area for 1926:

Number of deaths (exclusive of stillbirths) of infants under 1 year of age per 1,000 births, by color, for selected cities,[1] 1924, arranged by decreasing ratios for the colored

City	Deaths of infants per 1,000 births		City	Deaths of infants per 1,000 births

DEATH RATES IN A GROUP OF INSURED PERSONS

RATES FOR PRINCIPAL CAUSES FOR JUNE, 1926—COMPARISON BY WHITE AND COLORED FOR FIRST SIX MONTHS OF 1924, 1925, AND 1926

The accompanying tables are taken from the Statistical Bulletin for July, 1926, published by the Metropolitan Life Insurance Co. They present the mortality experience of the industrial insurance department of the company for June, 1926, as compared with May, 1926, and with June and the year 1925, and compare the rates for white and colored policyholders for the first six months of the years 1924, 1925, and 1926. The rates for 1925 and 1926 are based on a strength of approximately 17,000,000 insured persons in the industrial populations of the United States and Canada.

The death rate for June in this group of persons, 9 5 per 1,000, while higher than the rate for May, was lower than the rate for June a year ago This rate is stated to be about the average for June among these populations for the last five or six years.

Increased mortality rates over those for May were recorded for tuberculosis, cancer, cerebral hemorrhage, organic heart disease, Bright's disease, diarrheal diseases, accidents, and automobile fatalities Four of these causes—tuberculosis, cancer, cerebral hemorrhage, and automobile accidents—also registered higher death rates than in June, 1925.

The June death rate for influenza and pneumonia is stated to be considerably above the average for that month, and, in spite of the seasonal decline, the 1926 influenza outbreak was still showing its effect on the general mortality rate.

A high mortality from measles continued, the rate for June, 15 per 100,000, being next to the highest rate on the records of the company for that month.

Death rates (annual basis) for principal causes per 100,000 lives exposed, May and June, 1926, and June and year, 1925

[Industrial department, Metropolitan Life Insurance Co.]

Cause of death	Rate per 100,000 lives exposed [1]

[1] All figures include infants insured under one year of age
[2] Based on provisional estimate of lives exposed to risk in 1925

FIRST SIX MONTHS OF 1924, 1925, AND 1926

The Bulletin states:

Health conditions among the wage-earning populations of the United States and Canada during the first half of 1926 were not only less favorable than for the same period of last year but of any year since 1920. The increased mortality in the first six months of 1926 was due, for the most part, to above-average prevalence of influenza and pneumonia. It will be recalled that in 1920 the country experienced a very severe recrudescence of the 1918 influenza pandemic, resulting in a very unfavorable death rate during the early part of that year. But in the latter half of 1920 the health situation took a surprising turn for the better; and, when the year had run its course, it was found that the mortality of the industrial population had actually registered the minimum rate, up to that time. General population mortality statistics likewise showed that, with a single exception, 1920 had registered a lower death rate than any previous year. What occurred in the second half of 1920 suggests strongly that the 1926 influenza flurry constitutes, in itself, no real ground for pessimism as to the final health record for this year. It is still entirely possible that sufficient improvement will develop in the latter half of 1926 to counterbalance the high rate of the first half of the year. Up to July 10, the cumulative death rate of 1926 was only 4 per cent above that for the corresponding period of 1925.

Higher death rates for the first half of 1926 were also recorded for measles, whooping cough, organic heart disease, chronic nephritis, and cerebral hemorrhage, which more than counterbalanced the improvement shown for diphtheria, tuberculosis, diarrheal diseases, puerperal conditions, and accidents

It is predicted that the death rate for measles for the year 1926 will be the highest ever recorded for this group of persons since 1911, when mortality records were first kept by the company for individual diseases. The rate for the first half of this year, 17.6 per 100,000 white persons, was exactly four times as high as the rate for the corresponding period of last year

The increased mortality from the "degenerative diseases" is stated to be due in part to the influenza outbreak, which hastened the death of many persons suffering from these chronic conditions.

The death rate for tuberculosis among the white policyholders continued to decline The rate for the colored, on the other hand, showed an increase over both 1924 and 1925.

The rate for diarrheal diseases showed a decline among both white and colored persons. Marked improvement among the whites and a slightly better record for the colored were shown for diseases incidental to pregnancy and childbirth, although improvement in the principal item in this group of causes, puerperal septicemia, was confined to the white persons.

The number of deaths from alcoholism and from cirrhosis of the liver registered an increase over both 1924 and 1925. It is stated that a check of the company's mortality records, by quarters, over a long series of years reveals a seasonal incidence in mortality from alcoholism, more deaths, on the average, occurring during the first quarter of the year than in any of the other three-month periods.

An increase was again recorded for automobile fatalities among both white and colored persons.

Death rates (annual basis) for principal causes per 100,000 persons exposed for first six months of 1924, 1925, and 1926—Comparison of rates for white and colored policyholders

PUBLIC HEALTH ENGINEERING ABSTRACTS

Report of Committee on Bovine Diseases—Their Relation to the Milk Supply and to the Public Health. Dr. C D. Pearce, International Association of Dairy and Milk Inspectors Fourteenth Annual Report, October 12, 14, 1925, pp. 102–108. (Abstract by W. W. White.)

The United States Dairy Association estimates that from $100,000,000 to $130,000,000 was lost during the preceding year on account of bovine diseases among cattle. This does not include losses from parasites, exposure, and accidents.

A member of the committee, Dr. J. J. Fry, reports on the foot and mouth disease in California. During a period of five months, 23,086 herds of dairy cattle were condemned and slaughtered. No cases of the disease were reported in human beings and no transmission

occurred through the medium of dairy plant operation An outbreak of foot and mouth disease also occurred in Texas in September, 1924. Before the disease was stamped out, 148 herds in two counties had been slaughtered.

The most common disease in dairy cattle is grouped under the general term "mastitis." Physical examination by a competent veterinarian is of prime importance in educating dairymen regarding bovine diseases and their prevention, and in the disposition of undesirable cows.

As regards septic sore throat, it is still debatable as to whether it originates with cows or human beings.

The committee believes that bovine diseases and their relation to public health can be controlled by maintaining clean, healthy herds, producing clean wholesome milk, and by proper pasteurization of the milk

Report of Field Work Done by the Division of Milk Control During 1925. James R Kilborn, Laboratory Technician, Pennsylvania Department of Health Pennsylvania Association of Dairy and Milk Inspectors Second Annual Report, 1926, pp 74–76. (Abstract by J. R. Hoffert.)

In August, 1925, the Pennsylvania Department of Health placed a completely equipped motorized laboratory for testing the milk prepared and served in the communities of the State By cooperation with local officials, the milk supplies are tested for sedimentation, butter fat, specific gravity, keeping qualities, and bacterial counts, and pasteurization and other operations of milk plants are checked and the State milk laws enforced. Help is given in correcting defects noted and reinspections are made later. Material improvement in the milk supplies has already been noted.

DEATHS DURING WEEK ENDED AUGUST 7, 1926

[4] Deaths for week ended Friday, Aug. 6, 1926.

[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31, Baltimore, 15, Birmingham, 39, Dallas, 15, Fort Worth, 14, Houston, 25, Indianapolis, 11, Kansas City, Kans., 14; Memphis, 38, Nashville, 30, New Orleans, 26, Norfolk, 38, Richmond, 32; and Washington, D. C., 25

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week

State	Cerebrospinal meningitis	Diphtheria	Influenza	Malaria	Measles	Pellagra	Poliomyelitis	Scarlet fever	Smallpox	Typhoid fever
June, 1926										
South Dakota	2	10	8		184		1	234	25	8
Wyoming	1	7	1		39		0	56	2	3
July, 1926										
Arizona		6			16		0	12	0	9
Connecticut	2	47	2	4	394		1	121	0	23
New Mexico	0	16			9	5	0	6	0	30
Wisconsin	5	136	48		3,905		3	281	21	19

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended July 31, 1926, 37 States reported 759 cases of diphtheria For the week ended August 1, 1925, the same States reported 799 cases of this disease. Ninety-seven cities, situated in all parts of the country and having an aggregate population of more than 29,900,000, reported 464 cases of diphtheria for the week ended July 31, 1926. Last year for the corresponding week they reported 424 cases. The estimated expectancy for these cities was 552 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics

Measles.—Thirty-four States reported 2,052 cases of measles for the week ended July 31, 1926, and 668 cases of this disease for the week ended August 1, 1925. Ninety-seven cities reported 594 cases of measles for the week this year, and 401 cases last year.

Poliomyelitis —The health officers of 38 States reported 66 cases of poliomyelitis for the week ended July 31, 1926. The same States reported 226 cases for the week ended August 1, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 946 cases; last year, 692 cases, 97 cities—this year, 420 cases; last year, 308 cases; estimated expectancy, 261 cases

Smallpox —For the week ended July 31, 1926, 37 States reported 186 cases of smallpox Last year for the corresponding week they reported 174 cases. Ninety-seven cities reported smallpox for the week as follows: 1926, 28 cases; 1925, 53 cases; estimated expectancy, 39 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever —Nine hundred and twenty-four cases of typhoid fever were reported for the week ended July 31, 1926, by 37 States. For the corresponding week of 1925 the same States reported 1,141

cases of this disease. Ninety-seven cities reported 172 cases of typhoid fever for the week this year and 220 cases for the corresponding week last year. The estimated expectancy for these cities was 191 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 91 cities, with a population of more than 29,600,000, as follows: 1926, 285 deaths; 1925, 331 deaths.

City reports for week ended July 31, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[2] Dengue, 1 case at Atlanta, Ga
[3] Rabies (human), 1 case, 1 death, at Dallas, Tex, and 1 death at Los Angeles, Calif.

The following table gives the rates per 100,000 population for 102 cities for the five-week period ended July 31, 1926, compared with those for a like period ended August 1, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many

of the cities not being available The 102 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926 The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, June 27 to July 31, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

FOREIGN AND INSULAR

SMALLPOX ON VESSEL

Steamship "Karapara"—Development at quarantine, Durban, Union of South Africa[1]*—June 20-26, 1926.*—Later information dated July 9, 1926, received relative to the outbreak of smallpox on the steamship *Karapara*, at Durban, Union of South Africa, from oriental ports and Zanzibar, shows the development of two cases of smallpox in passengers landed from the vessel at Salisbury Island quarantine. The remaining passengers on the vessel were stated to be under strict surveillance.

THE FAR EAST

Report for week ended July 17, 1926.—The following report for the week ended July 17, 1926, was transmitted by the far eastern bureau of the health section of the League of Nations' secretariat, located at Singapore, to the headquarters at Geneva:

[1] One infected rat has been found in the port during the week.
[2] One infected rat has been found outside the port area.

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Iraq—Basra.
British India—Madras, Chittagong, Tuticorin.
Federated Malay States.—Port Swettenham.

[1] Public Health Reports, Aug 13, 1926, p 1747

Straits Settlements—Penang
Dutch East Indies—Batavia, Surabaya, Samarang, Belawan Deli, Palembang, Sabang, Makassar, Menado, Banjermasin, Balik-Papan, Tarakan, Padang
Sarawak—Kuching
British North Borneo—Sandakan, Jesselton, Kudat, Tawao
Portuguese Timor—Dilly
Philippine Islands—Manila, Iloilo, Jolo, Cebu, Zamboanga
French Indo-China—Turane
Formosa—Keelung
China.—Hongkong
Kwantung—Port Arthur, Dairen.
Japan.—Osaka, Nagasaki, Moji, Kobe, Niigata, Tsuruga Hakodate, Simonoseki
Korea—Chemulpo, Fusan
Manchuria—Antung, Mukden, Changchun, Harbin.
Union of Socialist Soviet Republics—Vladivostok

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.
New Guinea—Port Moresby
New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia.—Noumea.
Fiji—Suva
Hawaii—Honolulu.

AFRICA

Egypt—Port Said, Suez.
Anglo-Egyptian Sudan.—Port Sudan, Suakin.
Eritrea.—Massaua
French Somaliland—Jibuti
British Somaliland—Berbera.
Italian Somaliland—Mogadiscio.
Kenya—Mombasa
Zanzibar—Zanzibar
Tanganyika.—Dar-es-Salaam.
Seychelles—Victoria
Portuguese East Africa—Mozambique, Beira, Lourenço Marques
Union of South Africa—East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from:

British India.—Calcutta, Bombay, Vizagapatan, Cochin.
Dutch East Indies—Pontianak
Madagascar—Tamatave, Majunga.

CANADA

Communicable diseases—Two weeks ended July 31, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in six Provinces of Canada for week ended July 24, and in seven Provinces for week ended July 31, 1926, as follows:

WEEK ENDED JULY 24, 1926

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta [1]	Total
Cerebrospinal fever			1		2			3
Influenza	10							10
Lethargic encephalitis				1				1
Smallpox				9	1	1		11
Typhoid fever	2		5	8	2	3		20

WEEK ENDED JULY 31, 1926

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta [1]	Total
Cerebrospinal fever			1					1
Influenza	10							10
Smallpox				8		4		12
Typhoid fever			12	18	8		1	39

[1] No report for week ended July 24, 1926

CUBA

Governmental food inspection and drug control.—According to information dated July 9, 1926, the Department of Sanitation is making plans for the nationalization of food inspection throughout Cuba and the punishment of dealers who violate the pure food regulations, special attention to be given to slaughter-houses and butcher shops. It was stated that Señor Lopez del Valle, Chief of Sanitation of Habana, was to study the pure food law of the United States, with a view to the adoption of a similar law for Cuba

The Secretary of Sanitation is also reported to sponsor a measure designed to put the importation of opium and all other drugs directly under governmental supervision.

ECUADOR

Guayaquil—Plague-infected rats—July 1–15, 1926.—During the two weeks ended July 15, 1926, 10,020 rats were reported taken at Guayaquil, Ecuador, of which number 8 rats were found plague infected.

EGYPT

Plague—July 2–8, 1926—Comparative—During the week ended July 8, 1926, 8 cases of plague, of which one case occurred in the city of Alexandria, were reported in Egypt, making a total of 100 cases reported since January 1, 1926, as compared with 81 cases reported during the corresponding period of the preceding year.

MEXICO

Smallpox—Malaria—Diarrhea and enteritis—Chihuahua.—A report dated July 8, 1926, states that in April and May several cases of smallpox were reported at San Antonio de Arenales, principally among Mennonite colonists. In January, a disease diagnosed as malaria was reported among the colonists at San Antonio de Arenales and Santa Clara. Malaria is said to be rare in these localities, which are at an altitude of about 5,000 feet. Among the population are colonists from both the United States and the Ukraine. In June many deaths of children from diarrhea and enteritis occurred in Chihuahua.

PANAMA CANAL

Communicable diseases—June, 1926.—During the month of June, 1926, communicable diseases were reported in the Canal Zone, and at Colon and Panama, as follows:

Disease	Canal Zone		Colon		Panama		Infected in other localities		Total	
	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths
Chicken pox	2				5				7	
Diphtheria	1		1		6				8	
Dysentery	1				6		2		9

Malaria	205		13		11		56	3	285	3
Measles	2				4				6	
Meningitis			1						1	
Mumps	6		1						7	
Pneumonia [1]		1		3		15		3		22
Tuberculosis [1]		2		6		10		3		21
Whooping cough	1		1		4		1		7	

[1] Only deaths reported

PERU

Plague—June, 1926.—During the month of June, 1926, 34 cases of plague with 6 deaths were reported in Peru. The occurrence was in the departments of Cajamarca, Lima, and Piura. The greatest number of cases was reported in the coastal department of Piura and the district of Huancabamba, viz, 13.

UNION OF SOUTH AFRICA

Plague—June 20–26, 1926.—During the week ended June 26, 1926, six cases of plague with two deaths were reported in the Union of South Africa, occurring in the Cape Province. Of these, four cases with one death, in the colored population, and one fatal case in a European, were reported in the Calvinia district, and one case, colored, in Williston district. The occurrence was on farms.

PUBLIC HEALTH REPORTS

ISSUED WEEKLY

BY THE UNITED STATES PUBLIC HEALTH SERVICE

VOLUME 41 :: :: NUMBER 35

AUGUST 27 - - - 1926

SPECIAL ARTICLES

Characteristics of Blood Virus in Rocky Mountain Spotted Fever

Directory of State and Insular Health Authorities, 1926

WASHINGTON
GOVERNMENT PRINTING OFFICE
1926

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM
THE SUPERINTENDENT OF DOCUMENTS

PUBLIC HEALTH REPORTS

VOL. 41 AUGUST 27, 1926 NO. 35

ROCKY MOUNTAIN SPOTTED FEVER: CERTAIN CHARACTERISTICS OF BLOOD VIRUS

By R R SPENCER, Surgeon, and R R PARKER, Special Expert, United States Public Health Service

The experiments outlined below suggest that some of the virus in the blood of animals infected with Rocky Mountain spotted fever is inseparable from the red and white blood cells, that it has a strong affinity for the same cells of normal animals, that it can be easily separated from the platelets, and that it exists in a form not readily demonstrated by our present methods of staining In this connection it is interesting to note that Kusama (quoted by Segal) and Segal (1) reported that the virus of typhus fever was not associated with leucocytes or erythrocytes, but with the platelets.

The apparent disparity between the number of demonstrable organisms in the blood of animals infected with Rocky Mountain spotted fever, and the high degree of infectiousness of the same blood has often been noted.

Ricketts (2), for example, saw in the blood serum of infected man, monkeys, and guinea pigs an occasional "diplococcuslike body with an eosin-staining intermediate substance" These bodies could be "found in any preparation of infected blood during a search of not more than a half hour's duration." Ricketts has also shown that 0.7 c c. of red cells after the tenth washing was infectious, while 10 c. c. of the supernatant fluid after the tenth washing was not infectious. White cells after the third washing were infectious in 5 c. c. amounts. Smaller amounts of cell suspensions were not injected and the amount of the dilution after each washing was not given.

Wolbach (3) states that "the demonstration of the parasite in the circulating blood is extremely difficult."

Connor (4) by diluting spotted-fever serum five times with salt solution and centrifuging (2,000 revolutions per minute) for six hours was able to demonstrate in smears of the residue a few organisms identical with forms in tick and animal tissue described by Wolbach (3) and Nicholson (5). Connor says: "The unusual virulence of the blood (0.001 c c. often being infectious) seems somewhat incompatible with the exceedingly small number of organisms found."

EXPERIMENTS

Experiment No. 1: Effect of high-speed centrifugation on virus in cell-free serum.—The blood serum of two spotted-fever-infected guinea pigs was pooled and a sample removed to determine the minimal

infectious dose by injecting graded dilutions into guinea pigs (two animals to each dilution).

The remaining pooled serum was then centrifuged at 8,800 revolutions per minute for 15 minutes in a Leune centrifuge One cubic centimeter of the top was carefully removed and used for graded injections into animals as before. All of the remaining fluid, except 1 c. c. at the bottom, which contained a small amount of sediment, was discarded. This residue was similarly injected into animals in graded dilutions.

Result—The serum before centrifugation produced spotted fever in both animals receiving 1/500 c. c. but not in those receiving less amounts.

The top serum of the centrifuged portion produced spotted fever in guinea pigs receiving 1/10 c. c. but not in less amounts.

Injection of the lower centrifuged portion produced spotted fever in one of the guinea pigs receiving 1/100 c. c. but not in the other nor in those receiving less amounts.

Centrifugation for a longer period than 15 minutes was inadvisable because of the great amount of heat produced by the high-speed machine The heat was probably responsible for the decrease in infectivity of the centrifuged sediment.

In smears made from the top serum and stained with Giemsa's solution no organisms could be found A few scattered rickettsia-like forms could be found in smears of the lower portion.

Experiment No 2: Association of the virus with washed red cells.—The red cells of 12 c. c. of blood of a spotted-fever-infected guinea pig were washed three times with salt solution. The lower half only of the packed cells was then drawn off with a fine capillary pipette, care being taken not to draw up the thin top coat containing leucocytes and platelets. The pure red cells were then diluted to the original blood concentration, and 1 c. c. was used for graded dilutions and injected into guinea pigs. The remaining red cells were washed by centrifugation nine times more. Only three minutes were required for complete throwing down of the red cells at a speed of 1,200 revolutions per minute, and the clear supernatant salt solution was drawn off each time so that the packed red cells were left in a volume of less than 5 c. c. Salt solution sufficient to make a total volume of 40 c. c. was added after each washing, and the cells were thoroughly mixed. This method of washing was followed in all subsequent tests.

Result.—After the third washing the injection of 1/10 c. c. of red cells (diluted to the original volume) produced typical spotted fever in each of two guinea pigs and a moderate fever developed in one of two animals receiving 1/100 c. c. of cells. Smaller amounts failed to give fever.

Two guinea pigs receiving 4 c c. each of the supernatant salt solution of the twelfth washing were negative for 12 days and subsequently were found susceptible by reinoculation of blood virus.

Guinea pigs receiving 1 c c each of red cells (diluted to the original volume of the blood) after the twelfth washing and one of the pigs receiving 1/10 c c developed typical spotted fever. Less amounts failed to give fever We have found it impossible to demonstrate organisms of any kind within the red cells either in fresh preparations or in smear preparations stained with Giemsa's solution.

Experiment No. 3· Association of the virus with washed white blood cells.—A white-cells exudate obtained by injecting aleuronat into the peritoneal cavity of an infected guinea pig was suspended in 10 c. c. of salt solution and washed 12 times in the same manner as in the case of the red-blood cells The supernatant fluid after each centrifugation could be poured off, leaving a volume of less than 1 c. c of white cells The washing of these cells was therefore more thorough than that of the red cells.

Result—Guinea pigs receiving 1/100 c c of unwashed cells developed spotted fever. Less amounts failed

Guinea pigs receiving 1 c. c and one animal receiving 1/10 c. c. of the white cells after the twelfth washing, developed spotted fever. Less amounts were unsuccessful.

Experiment No 4: Adsorption of virus with normal red cells.—Five cubic centimeters of a cell-free serum obtained from an infected guinea pig was mixed with an equal volume of a suspension of washed normal red-blood cells After thorough agitation the mixture was permitted to stand one-half hour at room temperature. The red cells were then washed 10 times as in previous tests and injected as before in graded amounts.

Result—The two guinea pigs receiving 1 c. c and the two receiving 1/10 c c. of the washed cells developed spotted fever.

Experiment No 5· Adsorption of virus with normal white blood cells—Five cubic centimeters of cell-free guinea-pig serum virus was mixed with equal amounts of a suspension of normal guinea-pig leucocytes (½ gram of moist leucocytes in 5 c. c. of salt solution). The mixture was thoroughly shaken and permitted to stand one-half hour at room temperature and then washed 10 times by centrifugation. The washed cells were then diluted to the original volume of 5 c c. and injected into guinea pigs.

Result—Both animals receiving 1/10 c c. as well as the two receiving 1 c. c. of the washed cells developed spotted fever.

Experiment No. 6: Association of virus with platelets—(*a*) A 5 c. c. suspension of platelets obtained from 10 c. c. of blood of a spotted-fever-infected guinea pig was secured by the method of Kusama as reported by Segal (1). The unwashed suspension from the infected

animal produced spotted fever in 1/100 c c amounts when injected into guinea pigs After the third washing 1 c. c. amounts of the platelet suspension failed to produce spotted fever in each of two animals. Larger quantities were not used because so small an amount of the suspension was available.

(*b*) Three cubic centimeters of serum from an infected guinea pig were then added to 3 c c. of a platelet suspension obtained from 10 c c of blood of a normal guinea pig. One-tenth cubic centimeter of the unwashed mixture produced spotted fever, while 1 c. c. of platelets after the sixth washing failed to give fever when injected into each of two animals.

Experiment No. 7: Absorption of virus with fuller's earth.—Four cubic centimeters of serum virus was added to 4 c. c. of a sterile suspension of fuller's earth (½ gram of powdered fuller's earth in 40 c. c. of salt solution).

The mixture stood one-half hour at room temperature. Three cubic centimeters was set aside and the remaining 5 c. c. was washed 10 times by centrifugation as in previous tests upon cells. The washed and unwashed suspensions were injected into guinea pigs at the same time.

Results.—One-tenth cubic centimeter of the unwashed suspension produced spotted fever, while 1 c. c. of the washed suspension injected into each of four guinea pigs failed to give spotted fever.

The test was duplicated with the exception that finely ground charcoal was substituted for fuller's earth. The washed suspension likewise gave negative results.

DISCUSSION

In our tests we never were able to obtain an absolutely pure suspension of white cells or platelets. A few red cells could always be found when stained smears were prepared from such suspensions.

It was somewhat surprising to find that the virus was not retained by the platelets, especially since Kusama and Segal have shown that the virus of typhus fever is associated with the platelets but not with the red or white cells.

Inasmuch as the virus in the serum of animals infected with Rocky Mountain spotted fever can be thrown down only partially by high-speed centrifugation, one can not hold the view that the retention of the virus by both red and white cells (normal and infected) after slow centrifugation is due to the possession of the same specific gravity by the cells and virus. It is unlikely that the specific gravity of the virus would be such that it stratifies at the same level of both red and white cells. Furthermore, when mixed with a suspension of fuller's earth or charcoal and subjected to the same washing procedure it is not thrown down along with these particles. The test

strongly suggests, therefore, that part of the virus remains lodged within or adherent to the cells.

In a cytological study of rickettsia in tissues of guinea pigs infected with Rocky Mountain spotted fever, Nicholson (5) says: "In some tissues it required several hours' search with the aid of a mechanical stage and in others a day or more to find them * * *. In several cases also, they appeared to be present within erythrocytes." As illustration, he gives a single figure which bears the title, "One rickettsia apparently within an erythrocyte."

Fricks (6) has described, in the centrifuged red blood cells of infected animals, "round or slightly elongated red chromatin bodies partially surrounded by or in close approximation to a somewhat larger deep-blue staining body." Such bodies were never found in control specimens Fricks suggested that these bodies were of protozoan nature but hesitated to draw definite conclusions from his findings.

We are inclined to regard as highly significant the fact that, in the examination of hundreds of specimens of infected blood, rickettsia could not be demonstrated by us within erythrocytes, and yet the infective agent could not be washed or diluted away from such cells.

The difficulty with which rickettsia are demonstrated microscopically in tissues of infected animals is not compatible with the general, intense plasmatic and systemic infection as shown by animal inoculation, although we realize the possibility that a single organism or very few organisms may be infective. It seems likely, however, that the few rickettsia (*Dermacentroxenus rickettsi* Wolbach) found, represent, in part, one phase of the infective agent, but they do not convincingly represent all known manifestations of the blood virus. In this connection it may be stated that one receives the same impression when a study is made of the presence and distribution of rickettsia in the tissues of infected ticks (7).

Our tests might be regarded as suggesting that the virus of Rocky Mountain spotted fever can assume in the mammalian host a noncellular or nonparticulate phase which can not be demonstrated by our present known methods.

SUMMARY

1. The serum from guinea pigs infected with Rocky Mountain spotted fever and subjected to high speed (8,800 revolutions per minute) centrifugation retains infectivity in the top portion.

2 After repeated washings by slow speed (1,200 revolutions per minute) centrifugation, red and white blood cells from infected guinea pigs are capable of transmitting the infection although the demonstration of organisms in fresh preparations or stained smears of such cells is extremely rare.

3. Normal red and white blood cells to which serum virus has been added retain the infection after repeated washings by centrifugation.

4. A suspension of platelets from an infected guinea pig, as well as a suspension from a normal animal to which virus has been added, does not retain the infection after washing by centrifugation.

5. Suspensions of fullers' earth or charcoal to which serum virus has been added, quickly lose infectiousness when washed by centrifugation.

6. The suggestion is made that the virus of Rocky Mountain spotted fever may assume a form incapable of demonstration by known methods.

ERRONEOUS REPORT OF YELLOW FEVER IN NEW YORK CITY

An erroneous report of a death from yellow fever in New York City was made recently, due to an error in diagnosis. The cause of death appeared as yellow fever on the death certificate, and in this manner appeared in the weekly list of communicable diseases reported by the city department of health to the customhouse, where an employee of the Public Health Service inadvertently entered it on the port sanitary statement without bringing the matter to the attention of the medical officers. The port sanitary statements issued by the Public Health Service are used by the consuls of various countries in preparing bills of health. The yellow fever item appearing on bills of health quite naturally soon stimulated inquiries, especially in view of the fact that no official declaration of the case had been made by officials of the Public Health Service. In response to these inquiries, the Surgeon General promptly cabled the information that the report was erroneous and was due to an error in diagnosis.

The facts of the case are, briefly, as follows:

On July 3, 1926, a case was diagnosed as yellow fever from autopsy findings by a pathologist of a New York City hospital. Officers of the Public Health Service and officials of the New York City health department immediately investigated the case and found no justification for such a diagnosis. Unfortunately, however, the cause of death appeared as yellow fever on the death certificate, and in this way was included in the weekly reports made by the city health department to the customhouse, coming to the attention of the Public Health Service employee who makes out the port sanitary statements.

The patient was taken from a steamship belonging to a fruit company. The vessel had been last previously boarded and inspected at the New York quarantine station on May 25, 1926. On June 1 the vessel had sailed for Kingston, Jamaica, and since that date had sailed only between Kingston and Philadelphia It entered New York coastwise from Philadelphia on July 1 The patient had left Jamaica on the vessel on June 22 He died July 3, 1926.

Officials of the International Health Board state that there has been no case or suspected case of yellow fever in Jamaica for a great many years.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Public-health aspects of cross connections and dual water supplies. Matthias Nicholl, Charles A Holmquist, and Arthur S. Bedell. *American Journal of Public Health,* vol 16, No 4, April, 1926, pp. 355–364. (Abstract by C. M. Baker)

The authors tabulate some 41 outbreaks of typhoid fever caused by pollution of water supplies through faulty cross connections involving over 100 deaths since 1903

Report of the committee on private fire-protection service of the American Water Works Association in June, 1919; report of the committee on cross connections, by-passes, and emergency intakes on public water supplies, conference of State sanitary engineers, Boston, Mass , June, 1921, report of the action of the board of water commissioners, Hartford, Conn., 1920, and resolutions passed by the fire-protection section of the American Water Works Association at Louisville, Ky., April 30, 1925, are reviewed

In discussing double check-valves, information is given that an inspection in a city in New York State disclosed the fact that of 22 double check-valves, 6 sets were leaking in both valves, 15 in one

valve, and only 1 showed no leak. In another city 27 per cent of the installations were affording no protection, and only 1 out of 22 installations was tight in both valves.

Appended to the article is a bibliography of 58 references.

Studies on lactose fermenting bacteria. Fred Berry, chief, division of laboratories, Ohio State Department of Health, Columbus, Ohio. *American Journal of Public Health*, vol 16, No. 6, June, 1926, pp. 590–594. (Abstract by H A. Kroeze)

These studies were made to determine the nature of slow gas-forming organisms which are not infrequently found in the examination of public water supplies The studies were made on ground water supples, including almost every type of dug, driven, or drilled wells, and a few springs Samples (64) were collected in several series extending over a period from June to January. No seasonal difference was noted in the prevalence of slow lactose fermenters.

The writer gives a table showing the comparison of the rate of lactose fermentation, methyl red and Voges-Proskauer reactions, and growth in Koser's citrate medium, with comments on the results. A classification as to the source of the samples is also given

The writer concludes that "The results obtained in 640 samples of ground water confirm the opinion expressed by the committee on standard methods of water analysis that bacteria which do not produce 10 per cent or more gas in 48 hours at 37° C in 1 per cent lactose broth are of slight sanitary significance."

STATE AND INSULAR HEALTH AUTHORITIES, 1926

DIRECTORY, WITH DATA AS TO APPROPRIATIONS AND PUBLICATIONS

Directories of the State and insular health authorities of the United States for each year from 1912 to 1925 have been published in the Public Health Reports [1] for the information of health officers and others interested in public-health activities These directories have been compiled from information furnished by the respective State and insular health officers, and include data as to appropriations and publications.

Where an officer has been reported to be a "whole-time" health officer, that fact is indicated by an asterisk (*). For this purpose a "whole-time" health officer is defined as "one who does not engage in the practice of medicine or any other business, but devotes all his time to official duties."

EXAMINATIONS FOR ENTRANCE INTO THE REGULAR CORPS OF THE PUBLIC HEALTH SERVICE

Examinations of candidates for entrance into the Regular Corps of the United States Public Health Service will be held at the following-named places on the dates specified

Washington, D. C.	Oct 4, 1926.
Chicago, Ill.	Oct 4, 1926.
New Orleans, La.	Oct 4, 1926.
San Francisco, Calif.	Oct 4, 1926.

Candidates must be not less than 23 nor more than 32 years of age, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice. They must pass satisfactorily, oral, written, and clinical tests before a board of medical officers and undergo a physical examination.

Successful candidates will be recommended for appointment by the President, with the advice and consent of the Senate

Requests for information or permission to take this examination should be addressed to the Surgeon General United States Public Health Service, Washington, D. C.

DEATHS DURING WEEK ENDED AUGUST 14, 1926

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended August 7, 1926, 38 States reported 721 cases of diphtheria. For the week ended August 8, 1925, the same States reported 870 cases of this disease. Ninety-six cities, situated in all parts of the country, and having an aggregate population of about 30,000,000, reported 455 cases of diphtheria for the week ended August 7, 1926 Last year for the corresponding week they reported 474 cases. The estimated expectancy for these cities was 540 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-six States reported 1,614 cases of measles for the week ended August 7, 1926, and 586 cases of this disease for the week ended August 8, 1925. Ninety-six cities reported 380 cases of measles for the week this year, and 285 cases last year.

Poliomyelitis.—The health officers of 38 States reported 65 cases of poliomyelitis for the week ended August 7, 1926. The same States reported 296 cases for the week ended August 8, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-eight States—this year, 796 cases; last year, 773 cases; 96 cities—this year, 353 cases; last year, 291 cases, estimated expectancy, 248 cases.

Smallpox.—For the week ended August 7, 1926, 38 States reported 288 cases of smallpox. Last year for the corresponding week they reported 211 cases. Ninety-six cities reported smallpox for the week as follows: 1926, 43 cases; 1925, 50 cases, estimated expectancy, 43 cases. One death from smallpox was reported by these cities for the week this year—at Los Angeles, Calif.

Typhoid fever.—One thousand and seventy-five cases of typhoid fever were reported for the week ended August 7, 1926, by 37 States. For the corresponding week of 1925 the same States reported 1,329 cases of this disease. Ninety-six cities reported 161 cases of typhoid fever for the week this year and 225 cases for the corresponding week last year. The estimated expectancy for these cities was 208 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 91 cities, with a population of more than 29,300,000, as follows: 1926, 320 deaths; 1925, 302 deaths.

City reports for week ended August 7, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

The following table gives the rates per 100,000 population for 102 cities for the five-week period ended August 7, 1926, compared with those for a like period ended August 8, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 102 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, July 4 to August 7, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

Tanganyika.—Dar-es-Salaam.

Seychelles.—Victoria.

Mauritius.—Port Louis.

Portuguese East Africa.—Mozambique, Beira, Lourenço Marques.

Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

British India.—Calcutta.

Madagascar.—Tamatave, Majunga.

CANADA

Communicable diseases—Week ended August 7, 1926.—The Canadian Minister of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended August 7, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever			3	2				5
Influenza	5							5
Lethargic encephalitis	1							1
Poliomyelitis			1	1				2
Smallpox				2		12		14
Typhoid fever		2	3	8	9			22

ESTHONIA

Communicable diseases—June, 1926.—During the month of June, 1926, communicable diseases were reported in the Republic of Esthonia as follows:

Disease	Cases	Disease	Cases
Diphtheria	18	Scarlet fever	154
Leprosy	2	Smallpox	2
Measles	641	Tuberculosis	162
Paratyphoid fever	5	Typhoid fever	39

FRANCE

Plague—Marseille and vicinity of Paris—Information has been received under date of August 2, 1926, showing the occurrence of a fatal case of plague in a dock laborer at Marseille, France, July 8, 1926, and of a case, the date of occurrence not stated, at St. Denis, in the vicinity of Paris

GREAT BRITAIN (SCOTLAND)

Further relative to typhus fever outbreak—Glasgow—Information received under date of August 3, 1926, relative to seven cases of typhus fever at Glasgow reported that date,[1] shows that the cases occurred in the same family

HAWAII TERRITORY

Plague-infected rat—Paauhau—July 24, 1926.—A plague-infected rat was reported trapped at Paauhau, Hawaii Territory, July 24, 1926.

JAPAN

Plague—Plague-infected rats—Yokohama—July 6-21, 1926.—Under date of July 6, 1926, information was received of the occurrence of three fatal cases of plague at Yokohama[2] To July 21, 1926, six cases and the finding of four plague-infected rats were reported at Yokohama The occurrence was stated to have been in the locality of the canals used for landing cargo from lighters.

LATVIA

Communicable diseases—May, 1926.—During the month of May, 1926, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	2	Puerperal fever	2
Diphtheria	35	Rabies	1
Dysentery	3	Scarlet fever	241
Erysipelas	35	Tetanus	1
Lethargic encephalitis	1	Trachoma	34
Measles	199	Typhoid fever	46
Mumps	20	Typhus fever	7
Paratyphoid fever	3	Whooping cough	84

Population, estimated, 1,850,000

UNION OF SOUTH AFRICA

Plague—Cape Province—June 27-July 3, 1926—During the week ended July 3, 1926, two cases of plague were reported in the Cape Province, Union of South Africa. The occurrence was in the colored or native population of the districts of Calvinia and Williston.

[1] Public Health Reports, Aug 13, 1926, p 1750.
[2] Public Health Reports, July 16, 1926, p 1506.

Investigation of plague conditions in infected area—Information received under date of July 16, 1926, indicates that plague infection, which had been known to exist among veldt rodents in the Kenhardt District of the Cape Province for about two years, had recently spread south and southwest to the Calvinia and Williston Districts, extending south to a point half way between these districts and west as far as Nieuwoudtville. On June 11, 1926, a suspect case of plague in man and suspicious mortality among rodents in this area were noted. From that date to the present one case, fatal, in a European, and nine cases, with three deaths, in the colored population, have been reported. The area in which the cases occurred was stated to be heavily infested with Namaqua gerbilles (the rodent jerboa) and hares, these animals being also heavily infested with fleas. In three of the human cases reported the patients were stated to have handled or eaten dead hares. The cases were bubonic in type.

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg. Gen. B. J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain. (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

BIOLOGICAL PRODUCTS

ESTABLISHMENTS LICENSED FOR THE PROPAGATION AND SALE OF VIRUSES, SERUMS, TOXINS, AND ANALOGOUS PRODUCTS

There is presented below a list of the establishments holding licenses issued by the Treasury Department in accordance with the act of Congress approved July 1, 1902, entitled "An act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes."

The licenses granted to these establishments for the products mentioned do not imply an indorsement of the claims made by the manufacturers for their respective preparations The granting of a license means that inspection of the establishment concerned and laboratory examinations of samples of its products are made regularly to insure the observance of safe methods of manufacture, to ascertain freedom from contamination, and to determine the potency, or safety, or both, of diphtheria antitoxin, scarlet fever streptococcus antitoxin, tetanus antitoxin, botulinus antitoxin, antidysenteric serum, antimeningococcic serum, antipneumococcic serum, bacterial vaccines made from typhoid bacillus, paratyphoid bacillus A, and paratyphoid bacillus B, diphtheria toxin-antitoxin mixture, diphtheria toxin for Schick test, scarlet fever streptococcus toxin for Dick test, scarlet fever streptococcus toxin for immunization, and the arsphenamines, the only products for which potency standards or tests have been established.

The enumeration of the products is as follows: Serums are placed first, the antitoxins, being more important, heading the list. The other products are arranged generally in the order of their origin. The items in each class are arranged alphabetically.

Establishments Licensed and Products for which Licenses have been Issued

AMERICAN ESTABLISHMENTS

Parke, Davis & Co , Detroit, Mich —License No 1

Diphtheria antitoxin; scarlet fever streptococcus antitoxin, tetanus antitoxin, antianthrax serum; antidysenteric serum, antigonococcic serum, antimeningococcic serum, antipneumococcic serum, antistreptococcic serum, hemostatic serum (Lapenta), normal horse serum, thyroidectomized horse serum vaccine virus; rabies vaccine (Cumming), tuberculin old; tuberculin T R ; tuberculin B. E ; tuberculin B. F.; bacterial vaccines made from acne bacillus, acne diplococcus, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, prodigiosus bacillus, pseud.

diphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus; diphtheria toxin-antitoxin mixture, diphtheria toxin for Schick test, scarlet fever streptococcus toxin for Dick test, scarlet fever streptococcus toxin for immunization, animal [illegible] extract, animal food extract, vegetable food extract, pollen extract, modified bacterial [illegible] made from colon bacillus, gonococcus, paratyphoid bacillus A, paratyphoid bacillus B, pneumococcus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, [illegible] made from gonococcus, pertussis bacillus, pneumococcus, staphylococcus albus, staphylococcus aureus, and streptococcus.

H. K. Mulford Co., Philadelphia, Pa.—License No. 2:

Diphtheria antitoxin, erysipelas streptococcus antitoxin, perfringens antitoxin; scarlet fever streptococcus antitoxin, tetanus antitoxin, antianthrax serum, antidysenteric serum, antigonococcic serum; antimelitensis serum, antimeningococcic serum, antipneumococcic serum; antistreptococcic serum; normal horse serum, vaccine virus, rabies vaccine (Pasteur), rabies vaccine (killed virus), tuberculin old, tuberculin T. R., tuberculin B. E., tuberculin B. F., tuberculin protein free (Lyons); bacterial vaccines made from acne bacillus, cholera vibrio, colon bacillus, dysentery bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, micrococcus melitensis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, plague bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, sensitized bacterial vaccines made from acne bacillus, cholera vibrio, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, diphtheria toxin-antitoxin mixture, diphtheria toxin for Schick test, scarlet fever streptococcus toxin for Dick test, scarlet fever streptococcus toxin for immunization, pollen extract, animal epidermal extract, animal food extract, vegetable food extract, poison ivy extract, pneumococcus antibody solution.

Slee Laboratories, Swiftwater, Pa.—License No. 6:

Diphtheria antitoxin, tetanus antitoxin, normal horse serum; vaccine virus, bacterial vaccines made from colon bacillus, gonococcus, paratyphoid bacillus A, paratyphoid bacillus B, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus.

The Cutter Laboratory, Berkeley, Calif.—License No. 8:

Diphtheria antitoxin, tetanus antitoxin, antistreptococcic serum, normal horse serum, vaccine virus, rabies vaccine (Pasteur), rabies vaccine (killed virus); tuberculin old, tuberculin B. F.; bacterial vaccines made from acne bacillus, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus; diphtheria toxin-antitoxin mixture, diphtheria toxin for Schick test, pollen extract.

Bureau of Laboratories, Department of Health, New York City—License No. 11:

Diptheria antitoxin, scarlet fever streptococcus antitoxin, tetanus antitoxin; antimeningococcic serum; antipneumococcic serum, normal horse serum, vaccine virus, rabies vaccine (Pasteur); tuberculin old, bacterial vaccines made from gonococcus, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, diphtheria toxin-antitoxin mixture, diphtheria toxin for Schick test.

Lederle Antitoxin Laboratories, Pearl River, N. Y.—License No. 17:

Diphtheria antitoxin; scarlet fever streptococcus antitoxin; tetanus antitoxin; antianthrax serum; antidysenteric serum, antigonococcic serum, antimeningococcic serum, antipneumococcic serum; antistreptococcic serum, measles immune serum; normal horse serum, vaccine virus, rabies vaccine (Pasteur); rabies vaccine (killed virus); tuberculin old; tuberculin B. E.; tuberculin B. F.; bacterial vaccines made from acne bacillus, cholera vibrio, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, plague bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, staphylococcus citreus, streptococcus, and typhoid bacillus; diphtheria toxin-antitoxin mixture; pollen extract, poison ivy extract, poison oak extract; diphtheria toxin for Schick test; scarlet fever streptococcus toxin for Dick test, scarlet fever streptococcus toxin for immunization.

Bacterio-Therapeutic Laboratory, Asheville, N. C.—License No. 23:

Watery extract of tubercle bacilli (von Ruck), modified tubercle bacillus derivative (von Ruck).

G. H. Sherman, M. D., Inc., East Jefferson Avenue, Detroit, Mich.—License No. 30:

Bacterial vaccines made from acne bacillus, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, nonvirulent tubercle bacillus, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus; pollen extract.

The Abbott Laboratories, North Chicago, Ill.—License No. 43:

Bacterial vaccines made from acne bacillus, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, micrococcus catarrhalis, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus; pollen extract.

Dr W T McDougall, 422 Brotherhood Building, Eighth and Minnesota Avenue, Kansas City, Kans.—License No 49
Rabies vaccine (Pasteur)

St Louis Pasteur Institute, 3514 Lucas Avenue, St Louis, Mo —License No 50
Rabies vaccine (dilution method).

The Upjohn Co, Kalamazoo, Mich – License No 51
Bacterial vaccines made from colon bacillus, gonococcus, influenza bacillus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, pollen extract

E. R Squibb & Sons' Research and Biological Laboratories, New Brunswick, N J —License No 52·
Diphtheria antitoxin, erysipelas streptococcus antitoxin, scarlet fever streptococcus antitoxin, tetanus antitoxin, antimeningococcic serum, antipneumococcic serum; antistreptococcic serum, normal horse serum, vaccine virus; rabies vaccine (Pasteur), rabies vaccine (killed virus), bacterial vaccines made from acne bacillus, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, staphylococcus citreus, streptococcus, and typhoid bacillus, leucocytic extract from the horse, diphtheria toxin antitoxin mixture, diphtheria toxin for Schick test, scarlet fever streptococcus toxin for Dick test, scarlet fever streptococcus toxin for immunization, pollen extract, arsphenamine, neoarsphenamine, sodium arsphenamine, sulpharsphenamine, solution of arsphenamine

Dr James McL Phillips, 2057 North High Street, Columbus, Ohio —License No 54
Rabies vaccine (dilution method)

Eli Lilly & Co, Indianapolis, Ind —License No 56
Diphtheria antitoxin, erysipelas streptococcus antitoxin, scarlet fever streptococcus antitoxin, tetanus antitoxin, antimeningococcic serum, antistreptococcic serum, normal horse serum, vaccine virus, rabies vaccine (Harris), tuberculin old tuberculin T. R, tuberculin B E, tuberculin B F, bacterial vaccines made from acne bacillus, cholera vibrio, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, plague bacillus, pneumococcus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, diphtheria toxin-antitoxin mixture, diphtheria toxin for Schick test

Swan Myers Co, 219 North Senate Avenue, Indianapolis, Ind – License No 58
Bacterial vaccines made from acne bacillus, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, micrococcus catarrhalis, micrococcus tetragenus, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, pollen extract, scarlet fever streptococcus toxin for Dick test, scarlet fever streptococcus toxin for immunization

Gilliland Laboratories, Marietta, Pa —License No 63
Diphtheria antitoxin, scarlet fever streptococcus antitoxin, tetanus antitoxin, antimeningococcic serum antipneumococcic serum; antistreptococcic serum, normal horse serum, vaccine virus, rabies vaccine (Pasteur), tuberculin old, tuberculin B E, tuberculin B F, bacterial vaccines made from acne bacillus, gonococcus, influenza bacillus, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, diphtheria toxin antitoxin mixture; diphtheria toxin for Schick test

Antitoxin and Vaccine Laboratory, Department of Public Health, Commonwealth of Massachusetts, Jamaica Plain, Boston 30, Mass – License No 64
Diphtheria antitoxin; scarlet fever streptococcus antitoxin, antimeningococcus serum, antipneumococcus serum, vaccine virus, bacterial vaccines made from paratyphoid bacillus A, paratyphoid bacillus B, and typhoid bacillus, diphtheria toxin-antitoxin mixture; diphtheria toxin for Schick test.

United States Standard Products Co, Woodworth, Wis. –License No 65
Diphtheria antitoxin, scarlet fever streptococcus antitoxin, tetanus antitoxin; normal horse serum; bacterial vaccines made from acne bacillus, colon bacillus, gonococcus, influenza bacillus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid, bacillus B, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, diphtheria toxin-antitoxin mixture; diphtheria toxin for Schick test, scarlet fever streptococcus toxin for Dick test, scarlet fever streptococcus toxin for immunization.

D. L. Harris Laboratories, Metropolitan Building, St. Louis, Mo.—License No 66.
Rabies vaccine (Harris).

The Arlington Chemical Co, Yonkers, N Y.—License No 67·
Bacterial vaccines made from colon bacillus, micrococcus tetragenus, pneumococcus, staphylococcus albus, staphylococcus aureus, staphylococcus citreus, streptococcus, pollen extract, animal epidermal extract; animal food extract, vegetable food extract

Dermatological Research Laboratories, Philadelphia, Pa. (branch of Abbott Laboratories, Chicago, Ill.)—License No. 68:
Arsphenamine; neoarsphenamine; sulpharsphenamine; bismuth arsphenamine sulphonate.

H. A. Metz Laboratories, 122 Hudson Street, New York City – License No 69.
Arsphenamine; neoarsphenamine, sodium arsphenamine; silver arsphenamine, neosilver arsphenamine; sulpharsphenamine.

Synthetic Drugs and Diarsenol Laboratories, Buffalo, N. Y.—License No. 70:
Arsphenamine, neoarsphenamine, solution arsphenamine, sulpharsphenamine.
Hanson, Westcott & Dunning, Baltimore, Md.—License No. 76:
Suspension of arsphenamine, suspension of neoarsphenamine.
Mallinckrodt Chemical Works, St. Louis, Mo.—License No. 77:
Arsphenamine, neoarsphenamine, sulpharsphenamine.
Agricultural Experiment Station, College of Agriculture, University of Illinois, Urbana, Ill.—License No. [illegible]:
Botulinus antitoxin.
Powers-Weightman-Rosengarten Co., Philadelphia, Pa.—License No. [illegible]:
Arsphenamine, neoarsphenamine, sulpharsphenamine, compound of [illegible] with arsphenamine base.
Terrell Laboratories, Texas National Bank Building, Fort Worth, Tex.—License No. 81:
Rabies vaccine (killed virus).
Jensen-Salsbury Laboratories, Kansas City, Mo.—License No. 85:
Botulinus antitoxin, rabies vaccine (killed virus).
Cook Laboratories, [illegible] Lake Shore Drive, Chicago, Ill.—License No. 86:
Bacterial vaccines made from acne bacillus, colon bacillus, Friedlander bacillus, gonococcus, influenza bacillus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus; diphtheria toxin-antitoxin mixture.
The Neosol Co., 7[illegible] Kingsley St., Buffalo, N. Y.—License No. 90:
Solution of neoarsphenamine, solution of sulpharsphenamine.
Hollister-Stier Laboratories, 312 Old National Bank Bldg., Spokane, Washington.—License No. 91: Pollen extract.
DePree Laboratories, Holland, Michigan.—License No. 93:
Arsphenamine, neoarsphenamine.
The Jackson Infirmary, Jackson, Mississippi.—License No. 96:
Rabies vaccine (Pasteur), rabies vaccine (killed virus).
Medical Arts Laboratory, Medical Arts Bldg., Oklahoma City, Oklahoma.—License No. 98:
Rabies vaccine (killed virus).
Bureau of Laboratories, Department of Health, Lansing, Mich.—License No. 99:
Diphtheria antitoxin; bacterial vaccine made from paratyphoid bacillus A, paratyphoid bacillus B, and typhoid bacillus; diphtheria toxin-antitoxin mixture; diphtheria toxin for Schick test; scarlet fever streptococcus toxin for Dick test; scarlet fever streptococcus toxin for immunization.

FOREIGN ESTABLISHMENTS

Institut Pasteur de Paris, Paris, France.—License No. 11. Selling agents for the United States: Pasteur Laboratories of America, 366 West Eleventh Street, New York City:
Diphtheria antitoxin; tetanus antitoxin; antianthrax serum; antidysenteric serum, antiplague serum; antistreptococcic serum; bacterial vaccines made from cholera vibrio, plague bacillus, staphylococcus albus, and staphylococcus aureus.
Farbwerke Hoechst, vorm. Meister Lucius und Brüning, Hoechst am Main, Germany.—License No. 24. Selling agents for the United States: H. A. Metz Laboratories, 122 Hudson St., New York City.
Diphtheria antitoxin; tetanus antitoxin, antistreptococcic serum, normal horse serum, tuberculin old; tuberculin T. R.; tuberculin B. E.; tuberculin B. F.; bacterial vaccines made from cholera vibrio, gonococcus, staphylococcus albus, staphylococcus aureus, and staphylococcus citreus, typhoid bacillus; sensitized bacterial vaccine made from typhoid bacillus; arsphenamine; neoarsphenamine, sodium arsphenamine; silver arsphenamine; neosilverarsphenamine; sulphoxylarsphenamine.
E. Merck, Darmstadt, Germany.—License No. 31. Selling agents for the United States: Merck & Co., 45-47 Park Place, New York City: Tuberculin Ointment (Moro).
Connaught Antitoxin Laboratory, University of Toronto, Canada.—License No. 73:
Diphtheria antitoxin; tetanus antitoxin.
Les Etablissements Poulenc Frères, 92 Rue Vieille-du-Temple, Paris, III, France.—License No. 74. Selling agents for the United States: Geo. J. Wallau, 6 Cliff St., New York City:
Bacterial vaccines made from gonococcus, micrococcus tetragenus, pertussis bacillus, staphylococcus albus, staphylococcus aureus, and synococcus.
Laboratoire de Biochimie Médicale, 92 Rue Michel-Ange, Paris, France.—License No. 83. Selling agents for the United States: Anglo-French Drug Co., 1270 Broadway, New York City. Selling agents for Porto Rico: Chas. Vere, Box 216, San Juan, P. R.: Sulpharsphenamine.
Instituto Sieroterapico Milanese, Milan, Italy.—License No. 87. Selling agents for the United States, Neother Products Co., 50 Union Square, New York City: Antianthrax serum; bacterial vaccines made from gonococcus, pneumococcus, staphylococcus albus, staphylococcus aureus, staphylococcus citreus, and streptococcus; neoarsphenamine.
Boots Pure Drug Co., Ltd., Nottingham, England.—License No. 92. Selling agents for the United States: The United Drug Co., 43 Leon Street, Boston, Massachusetts: Arsphenamine diglucoside.
Etablissements Mouneyrat, Villaneuve-la-Garenne, Seine, France.—License No. 94. Selling agents for the United States: G. J. Wallau, 6 Cliff Street, New York City: Phospharsphenamine.

Institut National de Vaccinothérapie, 26 Rue Pages, Suresnes (Seine), near Paris, France —License No 95.
Selling agents for the United States Lee S Smith Manufacturing Co, Pittsburgh, Pa Bacterial vaccines made from colon bacillus, enterococcus, Friedländer bacillus, micrococcus catarrhalis, micrococcus tetragenus, pneumococcus, staphylococcus albus, staphylococcus aureus, and streptococcus.

Behringswerke, A. G., Marburg-am-Lahn, Germany —License No 97
Bacterial vaccines made from gonococcus, staphylococcus albus, and staphylococcus aureus.

ENDEMIC GOITER AND PHYSICAL DEVELOPMENT

I. IN CINCINNATI SCHOOL CHILDREN *

By Robert Olesen, Surgeon, and Neil E Taylor, Acting Assistant Surgeon, United States Public Health Service

INTRODUCTION

While the literature dealing with goiter is voluminous, references to the effects of the endemic type, as it is encountered in the United States, are relatively few and often unconvincing The etiology, pathology, physiology, distribution, and more recently the prevention of endemic goiter have all received marked attention At the same time it has seemingly been taken for granted that the manifestations of the affection are so obvious as to require neither recounting nor study

It has been asserted that endemic goiter is responsible for interference with nutrition and consequently with retardation of normal physical growth. In all probability such impressions have been intensified by contact with and study of simple goiter in regions of marked endemicity, where cretinism, myxedema, and deaf mutism are much more frequent than they are in this country Nevertheless the subject is a vital one and manifestly requires investigation and study before a conclusion can be reached as to the influence of simple goiter upon the physical development of adolescent boys and girls in the United States.

Function of thyroid in regulating growth.—The action of the thyroid gland in regulating metabolism has aptly been compared to the part played by the governor of an engine or the hairspring of a watch. The thyroid apparatus elaborates its secretion from raw materials in food and drink, being subject to constant call from the processes which regulate growth and govern regular bodily function. Presumably development proceeds normally when ample iodine is available and the thyroid is functioning efficiently

Trend of opinion in literature.—Many writers maintain that disturbance of thyroid function, such as occurs in well marked endemic goiter, hampers both mental and physical development. Not only

---

* Editorial Note —It should be borne in mind that the present study was limited to a single locality, having a moderate incidence of endemic goiter. (Compared with regions of marked endemicity, such as Switzerland, Austria, and Northern India, Cincinnati may be regarded as having only a slight incidence of goiter.) Therefore, the findings can not be accepted as being representative of all portions of the United States. By making further studies it will be possible to ascertain the effects upon physical development in areas of slight and marked goiter prevalence.

is the nutrition of the body disturbed, in their opinion, but growth and physical development are likewise seriously hampered. Moreover, the children affected are said to be below the standard of health and development, look frail, and become fatigued easily. There are a number of noteworthy features peculiar to most of the references relating to endemic goiter and physical growth:

1. There is a marked similarity in the references, suggesting that the statements were obtained from a common source.
2. There is a lack of evidence in support of the statements made.
3. There is no mention at any time of the size of the goiter; the blanket statements of deleterious effects cover all thyroid enlargements from the smallest to the largest.
4. No references are made at any time to locality, to incidence, mildness or severity of goiter, in so far as the goitrous conditions are encountered in the United States. There are, of course, numerous allusions to the severity of goiter and its sequelae in regions of great endemicity in foreign countries. However, goiter and its manifestations in the United States are less intense than in certain other countries and therefore the data are not strictly comparable.

Endemic goiter and overheight.—Despite the numerous contentions that growth is retarded by endemic goiter there is considerable evidence to show that height is actually increased in the presence of this malady. Comparisons of physical measurements in cases of colloid goiter by Hill, Brett, and Smith [1], with the average standards for height and weight, showed that a large majority were above height for age. Examinations of drafted men in the United States showed that tall men were particularly prone to goiter, both simple and exophthalmic [2].

Between these varying and often unsupported contentions regarding the influence of endemic goiter upon physical development there is apparently considerable opportunity for research having for its purpose the determination of the true status of the maladjusted thyroid in relation to growth. Particularly is it necessary that conclusions regarding this relationship in the United States be untinged by experiences in Switzerland, Austria, India, and other countries in which simple goiter is known to be responsible for such marked manifestations as cretinism, mutism, and idiocy.

METHOD OF SECURING DATA

In the present study the physical development of thyroid-normal and thyroid-enlarged children were compared by means of estimates and actual measurements. In securing the requisite data, use was

[1] E. Gardiner-Hill, P. O. Brett, and J. Forest-Smith. Adolescent Goiter. Some Factors of Significance. Quarterly Journal of Medicine, Oxford, 18, 133, January, 1925.

[2] Army Anthropology. The Medical Department of the United States Army in the World War, Vol. 15, Statistics, Part 1.

made of a form[3] devised by the child hygiene section of the Public Health Service. This form has the advantage of simplicity and yet provides ample information for comparative study. In order to insure uniformity of results, all data were obtained and recorded in a like manner by physicians experienced in work of this character. The "instructions for making physical examinations of children," also prepared by the child hygiene section of the Public Health Service, served as the guide for obtaining the various measurements and estimates.

The estimates made during the course of the study included opinions regarding nutrition and posture. Ten uniform measurements were made of each child, as follows. Standing height, sitting height, weight, chest circumference, chest width, chest depth, vital capacity, head length, head breadth, and head height.

Two thousand nine hundred and seventeen white children were included in the investigation. Of this number 1,341 were boys and 1,576 were girls. The ages of most of the children ranged between 11 and 15 years, during which period thyroid enlargement is very likely to be present, though not to the extent which prevails just after this period. In determining the degrees of thyroid enlargement the standards and classification developed during the Cincinnati survey[4] were followed.

In order to insure representative conditions the children examined were chosen from schools located in different parts of the city. Thus, 3 of the schools were located in the poorer sections of the community, 2 in sections of moderate economic status, and 1 in the best section of the city. In addition there was 1 vocational school, attended largely by part-time girl workers, and 1 junior high school.

In the six elementary schools visited the children examined attended the fifth, sixth, seventh, and eighth grades. In the vocational and junior high schools most of the children were older and attended higher grades. By this means of selection a cross section of the elementary-school population was obtained. Moreover, this cross section was representative of various school ages, grades, sections of the city, environment, and social status.

THE RESULTS

In the following section the results of the physical measurements of children with or without enlargement of the thyroid gland will be set forth by means of comparative tabulations and brief explanation.

Thyroid enlargement.—In Table 1 are displayed the number and percentage of each degree of thyroid enlargement among the 1,341 white boys and 1,576 white girls included in the study, according to

[3] Form 14.

[4] Robert Olesen: Thyroid Survey of 47,493 Elementary-School Children in Cincinnati. Pub. Health Rep., vol 39, No. 30, July 25, 1924, pp. 1777-1802. (Reprint No 941.)

age. Among the boys there were 515 instances of thyroid enlargement, a percentage of 38.4. A greater number of enlargements, 927, or 58.8 per cent, were recorded among the girls. Owing to the comparatively small number of some of the degrees of thyroid enlargement it was found desirable, for statistical purposes, to reduce the five degrees of enlargement, recorded during the examinations, to three. Thus, the "very slight" and "slight" enlargements were combined and termed "slight." "Moderate" involvement was allowed to stand. "Marked" and "very marked" thickenings were combined and called "marked." In making the various comparisons of measurements all degrees of thyroid enlargement were combined under a single heading. By far the greatest number of enlargements so included were of the slight variety.

TABLE 1.—*Number and percentage of each degree of thyroid enlargement among 1,341 white boys and 1,576 white girls in the Cincinnati public schools, for all ages and for each age between 11 and 15 years*

NUMBER OF CHILDREN

The number and percentage of each degree of thyroid enlargement at each age between 11 and 15 years, as well as for all ages combined, are also shown in Table 1. It will be seen that slight enlargements were more frequent among the girls—50.4 per cent, as against 37.2 per cent for the boys. Moderate and marked enlargements were approximately eight times more commonly encountered among the girls.

Relation of degree of thyroid enlargement to symptomatology.—Inasmuch as thyroid enlargements of marked degree are commonly supposed to exert more positive and decided influences than do slight enlargements, a word of explanation appears desirable at this point.

Probably the following explanation of Bram [5] covers this point most satisfactorily:

Assuming that reference is had to so-called simple or nontoxic goiter, situated in the usual position, above the sternum, in persons of noncretinous or nonmyxedematous make-up, and assuming that the thyroid gland is not enlarged to the extent of causing pressure symptoms upon the structures of the neck, I would state that, generally speaking, the size of a thyroid enlargement bears no relation to constitutional disturbances, and that neither stature nor other phases of the economy, structurally or physiologically, appear to be influenced by size of thyroid enlargement This opinion is based upon my 16 years of work with goiter patients, during which more than 9,000 cases were studied. This is an abstract statement, presenting, as all good rules do, frequent exceptions.

Nativity.—The question of racial susceptibility or immunity to goiter is one which has occasioned much conjecture. During the present study the place of birth of each child, and of his parents and grandparents, were carefully recorded. A child whose parents and grandparents, as well as himself, had been born in the United States was termed "native stock." In this way various combinations of birthplaces were noted.

Ninety-three and eight-tenths per cent of the children examined were born in the United States; probably 75 per cent of these were born in the city of Cincinnati or its environs. Of the 826 thyroid-normal boys, 45.3 per cent were of native stock, while 49.3 per cent of the 515 thyroid-enlarged boys were similarly classed. Slightly smaller percentages of girls, 42.5 per cent of the 647 thyroid-normal and 40 per cent of the 927 thyroid-enlarged, were also native stock.

The combinations of parental nativity are shown in Table 2. Among the boys of native stock 59.6 per cent had normal thyroids, while 40.4 per cent had some degree of thyroid enlargement. Compared with the boys of native stock, five of the groups in Table 2 had greater percentages while three groups had smaller percentages of thyroid-normal individuals. Because of their irregularity these tendencies are not particularly significant.

Forty-two and six-tenths per cent of the girls of native stock had normal thyroids and 57.4 per cent had some degree of thyroid enlargement. When the percentage of thyroid-normal girls of native stock is compared with the remaining groups in Table 2 it is apparent that there are smaller percentages of the same type in seven of the eight remaining groups. While the number of girls included in the present study is entirely too small to serve for the drawing of general conclusions, the data at least suggest that there is less thyroid enlargement among the native-born girls. However, much additional evidence is needed to strengthen this assumption.

Heretofore it has been widely believed that the nativity of parents and grandparents has had little to do with the presence or absence

[5] Dr. Israel Bram, Philadelphia, personal communication, May 7, 1926

of goiter in the child, provided the family has resided in a community sufficiently long to have suffered the iodine deprivation necessary to induce thyroid enlargement. However, additional information on this point is obviously required before the belief can be accepted as fact.

TABLE 2. *Number of children in certain groups based on nativity of child, parents, and grandparents, and number and percentage of thyroid-normal and thyroid-enlarged in each group*

Explanation:
(1) Native born (child, both parents, and 4 grandparents born in United States).
(2) Child, both parents, and 3 grandparents born in United States.
(3) Child, both parents, and 2 grandparents born in United States.
(4) Child, both parents, and 1 grandparent born in United States.
(5) Child and both parents born in United States.
(6) Child and 1 parent born in United States.
(7) Child born in United States, parents and grandparents born elsewhere.
(8) Child, both parents, and 4 grandparents born outside of United States.
(9) All other combinations of nativity.

Estimates of development and posture.—In judging development or nutrition the existing standards of height and weight were not considered. Instead, emphasis was placed on general appearance, condition of the skin, amount of subcutaneous fat, muscle tone, alertness, and vitality. During the examinations nutrition was classed as excellent, good, fair, and poor. It was found, however, that most of the estimates fell in the good and fair classes, few notations being entered in the extreme upper and lower groups. Consequently the numbers with excellent and good nutrition were combined, as were those with fair and poor nutrition. Similarly combinations of types of posture and physical build were also found to facilitate statistical interpretation.

Nutrition.—The percentages of good and fair types of nutrition among the children examined are displayed in Table 3. So far as the examiners were able to estimate, the nutrition of those with normal thyroids was consistently and considerably better than those with enlarged thyroids. Thus, 80.8 per cent of the thyroid-normal boys and 81.8 per cent of the thyroid-normal girls had good physical development, while 70.1 per cent of the thyroid-enlarged boys and

79 per cent of the thyroid-enlarged girls had the same state of nutrition. The same superiority among the thyroid-normal individuals, though slight in some instances, is also apparent in the separate age groups, with the exception of he 15-year old boys and the 11-year old girls.

TABLE 3.—*Percentage of good and fair states of nutrition of 1,204 white boys and 1,308 white girls in the Cincinnati public schools, at each age between 11 and 15 years, and according to presence or absence of thyroid enlargement*

Age	Thyroid status	Boys			Girls		
		State of nutrition			State of nutrition		
		Good	Fair	Number of observations	Good	Fair	Number of observations
11	Thyroid normal	78.9	21.1	85	66.2	33.8	66
	Thyroid enlarged	72.9	27.1	70	72.5	27.5	91

TABLE 4.—*Percentage of good, fair, and poor types of posture of 1,204 white boys and 1,308 white girls in the Cincinnati public schools, at each age between 11 and 15 years, and according to presence or absence of thyroid enlargement*

Age	Thyroid status	Boys				Girls			
		Type of posture				Type of posture			
		Good	Fair	Poor	Number of observations	Good	Fair	Poor	Number of observations
11	Thyroid normal	45.9	45.9	8.2	85	49.2	38.5	12.3	65
	Thyroid enlarged	42.9	48.5	8.6	70	46.2	41.7	12.1	91
12	Thyroid normal	48.5	45.6	5.9	136	53.5	33.6	12.9	101
	Thyroid enlarged	38.3	53.0	8.7	81	46.1	43.8	10.1	128
13	Thyroid normal	54.1	38.4	7.5	159	45.8	38.3	5.9	102
	Thyroid enlarged	49.1	42.1	8.8	114	38.3	51.3	10.4	154
14	Thyroid normal	53.5	39.5	7.0	185	53.2	37.5	9.3	139
	Thyroid enlarged	45.0	44.2	10.8	120	46.8	36.0	17.2	192
15	Thyroid normal	49.1	43.8	7.1	169	52.9	31.6	15.5	155
	Thyroid enlarged	52.9	35.3	11.8	85	39.5	36.2	24.3	271
All ages	Thyroid normal	51.0	42.0	7.0	826	51.0	37.0	12.0	649
	Thyroid enlarged	45.2	45.2	9.6	515	42.8	41.0	16.2	937

Posture.—The estimates of good, fair, and poor posture among the children examined are shown in Table 4. Good posture is consistently more frequent among both boys and girls of the several age groups who have normal thyroids. Conversely, fair and poor posture are found more frequently among those with thyroid enlargements.

Age-weight-height relationship.—The weight and height index of nutrition is subject to the limitation that the establishment of a practicable standard and norm is not feasible. Furthermore, if such a norm could be established an individual deviation in weight would not necessarily indicate an actual departure from normal health. However, the defects in a nutrition index do not seriously mitigate against the validity of comparisons between children with and without thyroid enlargement. In the present investigation the index of nutrition devised by Drs. B. T. Baldwin and T. D. Wood was used. The standards consist of average weights of children of each sex, by ages and standing height. In the application of this standard a variation of 10 per cent from the average is usually classed as normal, but anything below this point is said to indicate malnutrition. In Table 5 the percentages of those more than 10 per cent overweight and of those more than 10 per cent underweight are shown. These data have been prepared for thyroid-normal and thyroid-enlarged boys and girls of each age between 11 and 15 years and also for all ages combined. An examination of this table shows that overweight is, with a single exception, more frequent among the thyroid-normal boys and girls. The 11-year old boys with thyroid enlargement appear to have a slightly greater percentage of overweight than do those with normal thyroids.

TABLE 5.—*Percentage of thyroid-normal and thyroid-enlarged children who are more than 10 per cent over and percentage of those who are more than 10 per cent under the Baldwin-Wood weight-height-age standards, according to age and sex*

MORE THAN 10 PER CENT OVERWEIGHT

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
All ages	17.0	10.6	21.7	14.7
11	17.7	18.5	12.4	12.[illegible]
12	17.6	9.8	20.7	12.6
13	22.0	4.3	25.5	18.1
14	14.6	9.1	23.1	13.5
15	16.0	15.2	23.2	15.4

MORE THAN 10 PER CENT UNDERWEIGHT

Age	Boys Normal	Boys Enlarged	Girls Normal	Girls Enlarged
All ages	10.9	12.8	19.9	24.6
11	7.0	8.6	15.3	18.7
12	13.9	11.1	21.7	24.1
13	10.7	13.1	27.5	22.1
14	13.5	17.5	18.7	20.2
15	8.9	16.5	14.8	27.4

When average underweight is considered it is apparent that children with normal thyroids are less prone to this condition than are thyroid-enlarged individuals. There are two exceptions to this

statement. Greater percentages of 12-year old boys and 13-year old girls with normal thyroids are underweight than are those of the same age with enlarged thyroid glands.

AVERAGE MEASUREMENTS

In a further attempt to distinguish differences between the physical measurements of children with and without thyroid enlargement some averages have been calculated. Thus, in Tables 6 to 15, inclusive, the average standing height, sitting height, chest circumference, chest depth, chest width, vital capacity, head length, head breadth, and head height are displayed, consecutively. The average measurements are given uniformly in each table according to sex for each age between 11 and 15 years. With the exception of the average standing heights, which have been calculated in inches, and the average weights, which have been calculated in pounds, all of the measurements are in the metric system.

TABLE 6.—*Average standing height, in inches, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	55.4	54.2	54.6	56.6
12	57.4	57.1	57.8	58.6
13	59.2	59.3	61.4	60.2
14	61.9	61.5	62.0	62.4
15	63.9	63.9	62.8	63.1

Average standing height.—Inasmuch as several investigators have commented upon the fact that individuals with thyroid enlargement are, on the average, taller than those with normal thyroids, a study of standing and sitting heights of the children included in the Cincinnati study is interesting.

According to Table 6 the advantage in slightly greater height lies with the boys without enlargement of the thyroid, the exception being those in the 13-year group. In the 15-year group the measurements are equal. Therefore, it may be concluded that the comparison of measurements of standing heights among the boys fails to reveal marked differences.

The average standing heights of girls with thyroid enlargement are greater than in those without enlargement, the 13-year group being an exception.

Average sitting height.—Definite differences are apparent when comparisons are made of sitting height or stem length of the children examined (Table 7). The sitting height is consistently greater among

both boys and girls with thyroid enlargement, the single exception being the 11-year old boys.

TABLE 7.—*Average sitting height, in centimeters, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	71.6	71.4	71.3	72.4
12	73.2	73.5	74.6	75.4
13	74.9	75.5	77.2	77.4
14	77.8	78.3	79.9	80.2
15	80.5	81.1	80.0	80.8

Average weight.—It is interesting to note in Table 8 that the average weights of girls between 11 and 15 equal or exceed the weights of boys of corresponding ages. When the average weights of thyroid-normal and thyroid-enlarged children are compared it is apparent that those in the former group are consistently heavier. Thyroid-normal boys are, on the average, 5.6 pounds heavier than the thyroid-enlarged boys. All of the thyroid-normal girls are heavier than thyroid-enlarged girls of similar age except in the 11-year group, the average weight superiority of the first named group being 2.4 pounds.

TABLE 8.—*Average weight, in pounds, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years, and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	76	70.1	73	81.1
12	86	81.0	87	86.6
13	94	90.2	103	97.8
14	104	98.5	114	106.4
15	117	109.2	117	110.0

The average chest measurements, including circumference, transverse, and antero-posterior measurements, are displayed in Tables 9, 10, and 11. With a few minor exceptions all of the measurements are slightly greater among the children having normal thyroid glands.

Average chest circumference.—An examination of Table 9 shows that the average chest circumferences are slightly greater among the thyroid-normal boys with the exception of those in the 14-year group. Among the girls the average chest circumferences are greater in all of those with normal thyroids except the 11-year group.

TABLE 9.—*Average chest circumference, in centimeters, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years, and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	65 7	65 3	64.1	65 5
12	68 3	67 1	67 9	67 5
13	70 2	70 1	72 0	69.3
14	72 6	73.0	74.5	66 5
15	75 8	74 2	74 6	73 1

Average transverse chest measurements.—The average transverse chest measurements are shown in Table 10. These measurements are slightly greater among the thyroid-normal boys. In the 12-year group the measurements are identical among boys with and without involvement of the thyroid. The average transverse chest measurements are slightly greater among all thyroid-normal girls except those of the 11-year group.

TABLE 10.—*Average transverse chest measurement, in centimeters, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years, and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	22 2	20 3	21 4	21.8
12	23 0	23 0	22.8	22.7
13	23 8	23 4	24.0	23.6
14	24.8	24.6	24.9	24 4
15	26 1	25 3	25.3	24 8

Antero-posterior chest measurements.—It is apparent from Table 11 that the average antero-posterior chest measurements are slightly greater among thyroid-normal boys and girls with the exception of those in the 11-year group.

TABLE 11.—*Average antero-posterior chest measurement, in centimeters, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years, and presence or absence of thyroid enlargement.*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	17.7	18.3	17.1	17.2
12	18.2	18.0	18.5	17.7
13	18 8	18 5	19.0	18.5
14	19.7	19.4	19.9	19.1
15	20.4	20.1	19 9	18.1

Average vital capacity.—The average superiority in vital capacity of boys over girls ranges between 0.1 and 0.6 of a liter. These and other data are shown in Table 12. Among the boys the average vital capacity is very slightly greater among the thyroid-normal individuals in the 12, 14, and 15 year groups, equal in the 13-year group, and less in the 11-year group. Collectively, the average vital capacity is slightly greater among the boys with normal thyroids.

TABLE 12.—*Average vital capacity, in liters, of 1,204 white boys and 1,308 white girls in the Cincinnati public schools, according to ages between 11 and 15 years and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	2.0	2.5	1.9	1.9
12	2.3	2.2	2.1	2.1
13	2.4	2.4	2.3	2.3
14	2.8	2.7	2.6	2.4
15	3.1	3.0	2.5	2.5

The average vital capacity is the same among thyroid-normal and thyroid-enlarged girls of the 11, 12, 13, and 15-year groups. In the 14-year group the average vital capacity is slightly greater among the thyroid-normal girls.

Summarizing, it may be stated that a very slight advantage in increased average vital capacity apparently rests with the thyroid-normal children, a slightly greater advantage being among the boys than among the girls.

Head measurements.—In Tables 13, 14, and 15 average measurements of head length, head breadth, and head height are presented. It will be noted that the head measurements of the boys exceed those of the girls. There are also slight differences in average measurements between thyroid-normal and thyroid-enlarged individuals.

TABLE 13.—*Average head length, in centimeters, of 1,204 white boys and 1,308 white girls in the Cincinnati public schools, according to ages between 11 and 15 years and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	18.1	18.0	17.5	17.5
12	18.0	18.0	17.5	17.9
13	18.1	18.1	18.5	17.7
14	18.3	18.3	17.9	17.9
15	18.4	18.3	17.9	18.0

Average head length.—No significant or uniform differences in average head length was noted between thyroid-normal and thyroid-enlarged boys and girls. (Table 13).

Average head breadth.—The differences in head breadth among boys with normal and those with enlarged thyroids, as shown in Table 14, are at no time marked. However, thyroid-normal boys, except those in the 12-year group, have a slightly greater head breadth than have the individuals with enlarged thyroids.

TABLE 14.—*Average head breadth, in centimeters, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	14 5	14 0	14 0	14 1
12	14 4	14 5	14 2	14 3
13	14 5	14 4	14 3	14.2
14	14 5	14 4	14 4	14 3
15	14.6	14 5	14 4	14 3

Among the thyroid-normal girls of the 13, 14, and 15 year groups, the average head breadth is one-tenth of a centimeter greater than among the thyroid-enlarged. In the 11 and 12 year groups the difference just cited is reversed.

Average head height.—In Table 15 it is seen that average head height is slightly greater among the thyroid-enlarged boys. The average head height in each group is the same among the thyroid-normal and thyroid-enlarged girls except in the 12-year group, where it is slightly greater among the latter.

TABLE 15.—*Average head height, in centimeters, of 1,204 white boys and 1,398 white girls in the Cincinnati public schools, according to ages between 11 and 15 years, and presence or absence of thyroid enlargement*

Age	Boys		Girls	
	Thyroid status		Thyroid status	
	Normal	Enlarged	Normal	Enlarged
11	14.3	14.4	13.7	13 7
12	14 1	14.5	13 7	13.9
13	14.1	14 1	13 7	13 7
14	14.2	14 4	13 9	13.9
15	14 2	14.4	13.7	13 7

SUMMARY

1. For the purpose of determining the effect of endemic goiter upon physical development, 1,341 white boys and 1,576 white girls were examined in eight Cincinnati public schools.

2. Five hundred and fifteen, or 38.4 per cent, of the boys had some degree of thyroid enlargement, and 927, or 58.8 per cent, of the girls had such involvements.

3. There were 498 slight, 14 moderate, and 3 marked enlargements among the boys, and 794 slight, 109 moderate, and 24 marked thickenings among the girls. Slight enlargements were one and six-tenths times more frequent among the girls than among the boys. Moderate and marked involvements were approximately eight times more frequent among the girls.

4. Estimates of nutrition and posture, as well as 10 uniform measurements, were made of each child.

5. A record of the birthplace of each child, and of his parents and grandparents was also kept. The data suggest that thyroid enlargement is slightly less frequent among the girls who are native born. The available information on this point among the boys is insufficient for the making of satisfactory deductions.

6. According to the estimates of the examiners, better nutrition and posture were slightly more frequent among thyroid-normal boys and girls.

7. Considerably greater percentages of thyroid-normal children were more than 10 per cent overweight than were thyroid-enlarged individuals. Underweight was more frequent among thyroid-enlarged children.

8. There was little significant difference between the average standing heights of thyroid-normal and thyroid-enlarged boys. The standing heights of thyroid-enlarged girls were greater than those of thyroid-normal girls.

9. Average sitting height was consistently greater among boys and girls with thyroid enlargement.

10. The average weights of thyroid-normal boys and girls were greater than of those having enlarged thyroids.

11. Average chest circumferences, transverse, and antero-posterior chest measurements were slightly greater among children having normal thyroid glands.

12. There were very slight differences in average vital capacities between thyroid-normal and thyroid-enlarged children; the advantage found in this group apparently resting with the former, the greater advantage being with the boys.

13. There were no significant or uniform differences in head length between the thyroid-normal and thyroid-enlarged groups.

14. Thyroid-normal boys, except in the 12-year group, had slightly greater average head breadth than had the thyroid-enlarged. The differences were not marked among the girls.

15. The average head height was slightly greater among the thyroid-enlarged boys. Among the girls there were no significant differences.

COMMENT

In interpreting the results of the present investigation it should be recalled that the measurements and estimates were made in a relatively small group of children in a district of moderate goiter prevalence. Moreover, the majority of the children examined had endemic thyroid enlargements of small size.

Despite obvious limitations, the study has apparently shown that children with normal thyroid glands have a definite superiority in certain physical measurements. Consequently it may be assumed that thyroid-normal children are, to some extent, better developed physically. Thyroid-enlarged children, however, appear to have the advantage of slightly greater height, particularly in the sitting position.

Whether the results of this examination of a relatively small number of children indicate a constant, uniform, and significant difference in physical measurements of normal and thyroid-enlarged individuals can be ascertained only by further and more extensive investigations of similar character. Certainly the findings are suggestive and indicate the need for maintaining a normal thyroid gland lest a retarding influence be exerted upon physical growth.

CURRENT WORLD PREVALENCE OF DISEASE

REVIEW OF THE MONTHLY EPIDEMIOLOGICAL REPORT ISSUED JULY 15, 1926, BY THE HEALTH SECTION OF THE LEAGUE OF NATIONS' SECRETARIAT[1]

During the spring months cholera spread slowly to all parts of the Indo-Chinese peninsula. At the end of May and the beginning of June the incidence of cases was declining in British India, in Siam, and in southern Indo-China, but the disease was still spreading in the upper part of Indo-China, especially in the Province of Tonking and in Kwang-Chow-Wan, according to the data made available in the Epidemiological Report for July 15, 1926, published by the health section of the League of Nations' Secretariat.

Telegraphic reports from the Singapore bureau for the week ended July 3 reported one case of cholera at Shanghai, China, and the second week after that (July 11–17) 37 cases were reported. According to newspaper reports cholera spread rapidly in the Chinese

[1] From the Office of Statistical Investigations, U. S. Public Health Service.

sections of Shanghai in the beginning of August, and many persons died of the disease.

In British India, cholera deaths declined during May in nearly all the Provinces, and the total number of deaths reported for the four weeks ended June 5 was only 50 per cent of the number reported in the corresponding period of 1926. The Epidemiological Report comments as follows on the cholera situation in the various provinces:

The Punjab, Kashmir, and the North-West Frontier Province were entirely free from cholera; Bombay Presidency, practically free. United Provinces were but little affected, apart from an outbreak in the district of Azamgarh, and only three districts were infected in the Central Provinces. The cholera incidence decreased in May in Bengal, and moderately severe outbreaks were reported in Bihar from the districts Muzaffarpur and Cuttack only. The number of cases reported in Assam was relatively high. The epidemic in the southern part of Madras Presidency continued to decrease; only in the district of Trichinopoly was a certain recrudescence noted in May.

TABLE 1.—*Cholera deaths reported in the Provinces of India*

Province	1926		1925
	Apr. 10–May 8	May 9–June 5	May 10–June 6
North-West Frontier	0	0	29
Kashmir	0	0	4,050
Punjab	2	2	565
Delhi	0	0	3
United Provinces	350	422	166
Bihar and Orissa	3,070	1,745	2,250
Bengal	3,510	902	863
Assam	493	691	247
Central Provinces	124	178	60
Madras Presidency	438	415	1,408
Hyderabad	0	0	0
Bombay Presidency	1	5	1
Burma	737	551	146
Other Indian States	42	26	4
Total	8,767	4,937	9,801

The cholera outbreak in Bangkok reached its peak about the middle of May, and the number of new cases steadily diminished throughout June and July. In the last week of July only 5 new cases were reported, as compared with 362 cases in the week ended May 22. For Siam as a whole the figures are not so recent, but the number of cases seems to have reached a maximum in the week ended May 22, when 710 cases were reported, after which a sharp decline occurred, 414 cases being reported in the week ended May 29, 487 cases in the week ended June 5, and 391 in the week ended June 12.

Table 2 shows the number of cases reported from the various provinces of French Indo-China and from Kwang-Chow-Wan by 10-day periods.

TABLE 2.—*Cholera cases reported in French Indo-China and in Kwang-Chow-Wan June 1 to July 20, 1926*

Province	June			July	
	1-10	11-20	21-31	1-10	11-20
French Indo-China:					
Annam	10	88	30	34	34
Cambodia	175	128	218	181	125
Cochin-China	403	489	267	240	119
Tonkin	200	143	381	254	241
Kwang-Chow-Wan	1	42	28		

In the principal ports of the Far East, where cholera outbreaks were reported in the early summer, the situation was greatly improved at the end of July; Saigon and Cholon and Haiphong had no cases in the last two weeks of July; Rangoon reported one death in each of the last two weeks, and Negapatam reported one death the week ended July 24 and none in the last week

Plague.—"The plague incidence in Egypt increased slightly in June," states the Report; 41 cases were reported during the four weeks ended July 1, as compared with 30 cases during the preceding four weeks, and 21 cases during the first four months of the year. Apart from 4 cases at Suez, the cases occurred in three widely separated Provinces, namely, 21 cases at Beni-Suef and 3 at Girga, in Upper Egypt, and 13 at Beheira in Lower Egypt.

The plague outbreak in Tunisia, referred to last month, apparently reached a maximum in the early part of June and the incidence rapidly declined, although the infection spread from Kairwan Province to the Province of Susa. From the beginning of the outbreak, May 11, to June 31, 157 cases were reported in Kairwan, 14 in Susa, 2 at Kef, and 1 at Sfax. During the first 10 days of July, 6 cases were reported in Kairwan Province and 5 in the Province of Susa.

One case of plague was reported at Constantinople on June 3, one case at Patras, Greece, on June 7, and at Algiers one case was reported in the period June 21 to 30 and one July 1 to 10.

Plague incidence increased markedly in Uganda during April and May. The season of high prevalence is normally from May to September. The cases reported in each week are shown in Table 3.

TABLE 3.—*Plague cases and deaths reported in Uganda, by weeks, from April 4 to June 12, 1926*

Week ended—	Number of cases	Number of deaths	Week ended—	Number of cases	Number of deaths
Apr. 10	10	10	May 15	53	43
Apr 17	29	23	May 22	67	48
Apr. 24	29	24	May 29	101	64
May 1	35	32	June 5	54	38
May 8	58	47	June 12	82	58

In Senegal an outbreak of plague occurred in May, and 129 cases with 71 deaths were reported, as against 12 cases in April.

In Kenya and Madagascar a slight recrudescence in plague occurred in June. Cases reported in Kenya for the four months March, April, May, and June numbered 81, 37, 40, and 79, respectively. For the same months, cases in Madagascar numbered 186, 103, 26, and 66.

The number of new cases of plague at Baghdad began to decline in the latter part of May; 40 cases were reported in the city in the two weeks ended June 5, as against 83 in the preceding two weeks, and 31 cases were reported in the two weeks ended June 19. Cases were also reported from the surrounding district.

In India the deaths from plague showed a gradual decline during May. The plague situation in the present year has been quite favorable except in the northwestern part of the country, particularly in the Punjab, where 15,350 deaths were reported in the four weeks ended June 5, as against 1,148 in the corresponding four weeks of 1925.

TABLE 4.—*Plague deaths reported in India from March to June 1924-1926*

Fortnight ended—	1924	1925	1926
Mar 13	18,407	8,606	10,558
Mar. 27	21,756	11,911	14,229
Apr 10	25,656	9,468	18,345
Apr 24	30,916	8,477	17,435
May 8	24,877	5,031	16,277
May 22	20,588	1,679	13,889
June 5	14,131	938	8,704
June 19	8,070	1,084	

In French Indo-China there were 21 cases of plague reported during June in Cochin-China. At Kwang-Chow-Wan 12 cases of plague were reported in May and 18 cases from June 10 to 19. Plague has been reported in several localities in southern China, but none at either Shanghai or Hongkong. At Amoy 90 cases of plague were reported from May 1 to July 10.

At Yokohama three cases of plague were reported in the week ended July 10.

Typhus fever.—The incidence of typhus fever was less during the past winter, on the whole, than during the winter of 1924–25 in eastern Europe, but its seasonal decline in the spring was somewhat retarded and, therefore, in the late spring the incidence became higher than in the corresponding period of 1925 in a number of countries. The report gives the following summary of the situation in eastern Europe:

Typhus was thus but little less in evidence in Poland in May than in April; 437 cases were reported during the four weeks ended June 5, as against 518 cases during the preceding four weeks, and 402 cases during the corresponding period of 1925. Similarly, there were 66 typhus cases in May in Lithuania, as against

68 in April and 40 in May, 1925. The outbreak in Sub-Carpathian Ruthenia has come to an end; only 6 cases were reported in May and 1 during the first half of June. Hungary remained free from typhus except for 1 case. In Rumania 354 cases were reported in April, as against 384 during the previous month and 153 in April, 1925.

In the U. S. S. R., March returns were, in general, low and differed little from those of the previous month with the exception of western Russia, where there was a certain recrudescence of typhus in the Governments of Smolensk, Pskov, and Gomel. Data for White Russia are not as yet available.

Typhus fever cases were reported by the countries in northern Africa as follows: 214 cases in Algeria and 296 cases in Tunisia in the first six months of 1926; 579 cases in Morocco during the first five months; 631 cases in Egypt during the first 20 weeks of the year.

Relapsing fever.—Relapsing fever was rare in Europe outside of Russia during the first half of 1926. In Poland 7 cases were reported in the first 5 months; in Lithuania 2 cases were reported in the same period; and in the Kingdom of the Serbs, Croats, and Slovenes 1 case was reported down to June 14.

In Russia the March reports showed a decrease in cases compared with the preceding two months. The disease has become rare in the northern part of the country, but was more common in the Black Earth district, on the Volga, and in the Caucasus, though no government reported as many as 100 cases in March.

Smallpox.—The smallpox outbreaks in Japan, Kwantung, and South Manchuria were abating at the end of May. In Japan only 31 cases were reported in the week ended June 5, as against 80 and 150, respectively, during the two preceding weeks. In Korea little change in the prevalence of the disease was indicated; 180 cases were reported in May, 168 in April, and 200 in March.

The incidence of smallpox in northern England was decreasing at the end of June, but was higher than that recorded at the corresponding season during any of the last 20 years. Four hundred and fifty-six cases were reported during the 3 weeks ended July 3, as compared with 614 in the preceding 3 weeks.

Enteric fever.—"The incidence of enteric fever was, everywhere in Europe, lower in May than during the corresponding period of 1925," states the Report. In Italy and Germany an increase in incidence was noted in the June reports. During the four weeks ended June 19, 606 cases were reported in Germany as compared with 403 during the preceding four weeks.

In Japan typhoid fever was more prevalent during the first five months of the current year than at the corresponding season for several years past; 14,804 cases of typhoid and 926 paratyphoid cases were reported between January 1 and May 29, as against 11,634 typhoid and 669 paratyphoid cases during the corresponding period of 1925.

Dysentery.—A lower incidence of dysentery was indicated by the reports for May and the early part of June in nearly all European countries.

In Japan the summer rise in dysentery began in May, with 695 cases reported during the four weeks ended June 5 as compared with 292 cases during the preceding four weeks.

Influenza.—A considerable prevalence of influenza in Russia was indicated, with 637,535 cases reported for the whole country in March, as compared with 316,137 cases in March, 1925.

In previous reports reference has been made to the widespread prevalence of influenza during March and April both in Europe and the United States. Mortality data available show that the number of deaths from this cause declined markedly during May.

Tanganyika Territory reported an influenza outbreak in April, with 1,200 notified cases.

Acute poliomyelitis.—"Data for the month of May showed a low prevalence of poliomyelitis both in Europe and in the United States, and no summer increase had begun. The incidence was somewhat higher than normal in Australia during the first months of the year, but decreased in May; 135 cases were reported during the first 20 weeks of 1926, as compared with 121 cases during the corresponding period of the previous year. During the same period there were only 9 cases of poliomyelitis in New Zealand, where a serious epidemic occurred in 1925, 1,230 being reported in the corresponding 20 weeks."

Scarlet fever and diphtheria.—Both scarlet fever and diphtheria were declining in incidence during the spring months in countries of the Northern Hemisphere, where the seasonal minimum normally occurs in the summer months.

Puerperal fever. The Epidemiological Report this month publishes a table showing the cases of puerperal fever notified in the various countries during 1924, 1925, and the first quarter of 1926. In many European countries this disease is notifiable, but an extremely wide range in the incidence is indicated and "it appears that the notification is hardly seriously enforced in more than a small number of European countries."

PASTEURIZATION OF MILK AND THE NONPULMONARY TUBERCULOSIS DEATH RATE IN NEW YORK CITY [1]

The practice of pasteurizing New York City's milk was started in 1912. At that time approximately 50 per cent of the milk consumed in New York City was subjected to pasteurization. In 1914 the

[1] From the Weekly Bulletin, August 21, 1926, published by the Department of Health of the city of New York.

pasteurization of all milk, save that grade termed certified, was made obligatory by law. The results of this practice are vividly reflected in our nonpulmonary tuberculosis rates. The table below clearly shows the constantly declining death rate for nonpulmonary tuberculosis.

Nonpulmonary tuberculosis death rates in New York City, 1910–1925

Year	Rate per 1,000 population	Year	Rate per 1,000 population
1910	0 29	1918	0 24
1911	30	1919	20
1912	28	1920	.17
1913	.28	1921	14
1914	27	1922	.13
1915	27	1923	.12
1916	23	1924	.14
1917	.24	1925	.12

Of even greater significance than the declining death rate for nonpulmonary tuberculosis is the fact that the examination of tuberculous glands of the neck made in the years previous to pasteurization, revealed that in more than 50 per cent the process was due to the bovine bacillus, whereas in only six of 50 specimens obtained since pasteurization has become general, was the bovine bacillus found, and five out of these six cases were from out-of-town patients who had been fed on raw milk.

The subject of pasteurization is now being actively discussed by health authorities. There is a considerable difference as to the degree of temperature to which the milk to be pasteurized should be exposed. Commercial interests and even certain scientists of very high repute oppose an increase in the temperature employed for pasteurization above 142° F. The Conference of State and Provincial Health Authorities of North America meeting with representatives of the United States Public Health Service in Washington, D. C., on May 24, 1926, unanimously agreed upon a temperature of 145° F. maintained for 30 minutes as the standard for pasteurization. Many cities, fearing that a lower temperature does not give an adequate margin of safety, have adopted the 145° F. standard as their legal requirement. The safety of the lower standard—142° F.—which is the legal requirement in New York City, is therefore brought into question. The commercial interests protest against a higher standard as being unnecessary and claim that if the present thermal requirement is raised, it will necessitate the installation of new equipment and increase the cost of milk to the consumer. They agree, however, that safety is the paramount and primary consideration. The Department of Health of the City of New York is committed to the latter principle, and the commissioner of health is now making a careful

but rapid inquiry to make sure whether we are justified in adhering to our present standard, or whether, in the interest of safety, 145° F. should be made the legal standard even at the sacrifice of a little of the cream line.

A decision will be made only after due consideration and study of the opposing viewpoints, and after conference with those who are qualified to give counsel and testimony.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Experiences with Cross Connections in Chicago. Arthur E. Gorman, Chief Sanitary Engineer, Division of Water Safety Control, City of Chicago. *Journal of the American Water Works Association*, Vol. 15, No. 6, June, 1926, pp. 587–599. (Abstract by Arthur E. Gorman.)

A two years' survey of cross connections in the public water system in Chicago located 491 such connections, 194 of which were of the direct or dangerous type. There were 297 indirect cross connections, such as connections on the suction of pumps, but constituting a relatively low public health risk. The policy followed in Chicago was to require the physical disconnections of direct cross connections, while indirect connections already in existence were permitted where the danger was relatively remote.

The cross connection work was developed with a minimum amount of friction with big industries and with excellent cooperation with the fire underwriters. The sizes of cross connections ranged from ½-inch to 18 inches, the more frequent being—

2-inch (21.4 per cent).
3-inch (14.0 per cent).
4-inch (11.6 per cent).
¾-inch (10.8 per cent).

Special studies were made of cross connections between private water systems within institutions and the public sewers. Dangerous connections were found between swimming pools and pressure filters used on drinking water systems in private institutions, such as apartment hotels and clubs, on account of the frequent backflow of sewage due to flooding of the main sewers. Several types of cross connections are discussed and illustrated by diagrams.

Pollution Affecting Navigation or Commerce on Navigable Waters. Report from Chief of Engineers, United States Army. House of Representatives Document No. 417, Sixty-ninth Congress, first session, June 4, 1926, 28 pages. (Abstract by J. K. Hoskins.)

This is a report of the Chief of Engineers, "giving the results of the investigation, authorized by section 9 of the oil pollution act, of 1924, on the general subject of pollution affecting navigation or

commerce on the navigable waters of the United States or the fisheries therein, together with recommendations for remedial legislation."

Polluting substances contributed to watercourses are divided into two general classes: (1) Domestic sewage and (2) industrial wastes, among the most injurious of which are (*a*) oil, (*b*) coal mining, (*c*) coal distillation, (*d*) metal trades, (*e*) pulp and paper mills, (*f*) tanneries, (*g*) textile, (*h*) miscellaneous.

The source and nature of each of these classes of wastes are briefly discussed, as well as their effect on navigation, commerce, and fisheries. It is stated that, "except in isolated and unimportant instances, the pollution of waters by domestic sewage and industrial wastes does not directly interfere with commerce or commercial navigation." Acid wastes indirectly affect the boilers and hulls of boats and metal parts of locks and dams, necessitating more frequent repairs. Floating oil creates an extra fire hazard but contributes little danger as an origin of fire because it is difficult to ignite. Fisheries are directly affected by toxic products in industrial and oil wastes. Untreated domestic sewage contains little or nothing that is toxic to aquatic life, and the addition of such sewage to the waterways up to a certain pollution density is beneficial to fish life because of the decomposition products, carbon dioxide and nitrates, which stimulate growth of aquatic plants and thereby produce fish food.

A table is included giving a list of navigable and nonnavigable waters into which polluting substances are being deposited to such an extent as to endanger or interfere with navigation and fisheries, the nature of pollution and its effect in each instance being stated in general terms. A summary of the more important findings is given.

Existing Federal laws relating to the pollution of navigable waters are cited, as well as the extent to which each of the States has adopted legislation dealing with pollution in State waters. Interstate agreements for pollution control are briefly mentioned.

The conclusions and recommendations deal with (*a*) fisheries and (*b*) commerce and navigation. In regard to fisheries, while certain streams are now too seriously polluted to support fish life, the economic factors involved do not justify prohibition of such pollution, since, as a general rule, "the value of the products of the fisheries is small as compared to the total value of the products of all the industries which use the waters." Should the Federal Government undertake control of pollution generally, it is probable that State and local authorities would tend to relax their efforts both of study and of law enforcement, "with the result that the entire problem would be left to the Federal Government, which would be confronted with the necessity for providing a large organization to cope with the many local problems which would arise," and accord-

ingly no Federal legislation is recommended so far as the effect of pollution of fisheries is concerned. Federal agencies, such as the Public Health Service, the Bureau of Mines, and the Bureau of Fisheries, are available to communities for assistance in studying their pollution problems.

In regard to the effect on navigation and commerce, Federal legislation for the prevention of pollution by acid mine drainage is not recommended, pending further information on the subject and because the State courts are able to redress individuals or corporations for damages resulting from such pollution. Federal jurisdiction over oil pollution should be extended to include control of such pollution from any source, so that the department may be in a position to cope with all such situations in any of the tidal waters of the United States, as well as those of the Great Lakes. (The act of 1924 applies only to the discharge of oil from oil-burning or oil-carrying vessels).

Studies in Regard to the Lighting of Post Offices, Made by the United States Public Health Service. James E. Ives and Edgar Sydenstricker. *Journal of Industrial Hygiene*, vol. 8, No. 5, May, 1926, pp. 232–247. (Abstract by Leonard Greenburg.)

This paper presents the results of lighting studies made during the years 1921–1923 in the general and City Hall post offices, New York City. These post offices differ in that in the City Hall office practically the only sources of illumination are artificial, while in the general post office 40 per cent is natural. In both offices the artificial illumination averaged about 3.5 foot candles; but this average is misleading, for the illumination was found to be better in the general post office, due to the natural illumination present. Examination of the vision and eye defects of 2,419 employees in these offices revealed a larger number of defects and a smaller percentage of normal vision in the City Hall than the general post office.

The percentage of normal vision in one or both eyes was found to vary with age, being approximately 75 per cent at 22 years of age and falling to 20 per cent at about 57 years of age. These figures were confirmed by other studies, by the investigators of the United States Public Health Service, on nearly 5,000 native white school boys and nearly 6,500 white industrial workers. It was also found that visual acuity was low at 5 years of age (among the school children) and reached a peak at 18 years. The least change in visual acuity was found to occur between the ages of 25 to 45 years. It was found that those persons doing the most intensive eye work have the poorest vision and the greatest number of eye defects.

Since the comparative studies in the two post offices indicated better vision and fewer defects in the well-illuminated office, it seemed reasonable to suppose that at he City Hall post office more illumination was necessary. Card-sorting studies and tests were therefore inaugurated in order to find the relation between speed of sorting and illumination, it being assumed that the illumination yielding the higher sorting rate would be that which would be best for the eyes. Accordingly, the speed of sorting 1,000 typed white cards under various degrees of illumination ranging from 2.8 to 14 foot candles was determined for three groups of workers having vision of 20/20, 20/20 to 20/30, and 20/30 to 20/40, respectively. It was found that those persons having 20/20 and 20/20 to 20/30 reached their maximum rate of production at 8 foot candles and this, plus a 20 per cent allowance for deterioration (making 10 foot candles), has been suggested as a standard.

The authors discuss the various tests which have been suggested or used for the determination of the sufficiency of illumination. It appears that the rate of production method is one of the most satisfactory methods, and the authors have therefore used this method in their further studies on lighting

In the studies on production rates, six series of tests were made under different conditions of illumination, each test of three or four days' duration. The amount of mail sorted by each of eight clerks in the dispatching and in the delivery departments was counted with the illumination varying from 3 3 to 7.7 foot candles. Curves are given for the relation between production rate and illumination.

Several interesting questions are raised at the close of the paper, on which is based the present work of the Public Health Service in these investigations. The two most interesting are (1) the question of why there is a lag in production when illumination is changed, and (2) the determination of ocular fatigue under different degrees of illumination.

DEATHS DURING WEEK ENDED AUGUST 21, 1926

Summary of information received by telegraph from industrial insurance companies for week ended August 21, 1926, and corresponding week of 1925 (From the Weekly Health Index, August 25, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Aug. 21, 1926	Corresponding week, 1925
Policies in force	65, 090, 898	60, 810, 078
Number of death claims	10, 020	8, 830
Death claims per 1,000 policies in force, annual rate	8. 0	7. 6

Deaths from all causes in certain large cities of the United States during the week ended August 21, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, August 25, 1926, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population.
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Data for 62 cities.
[4] Deaths for week ended Friday, August 20, 1926.
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population. Atlanta 31, Baltimore, 15, Birmingham 39, Dallas 15, Fort Worth 14, Houston 25, Indianapolis 11, Kansas City, Kans., 14, Louisville 17, Memphis 38, Nashville 30, New Orleans 26, Norfolk 38, Richmond 32, and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

CURRENT WEEKLY STATE REPORTS

These reports are preliminary and the figures are subject to change when later returns are received by the State health officers

Reports for Week Ended August 28, 1926

ALABAMA

	Cases
Chicken pox	4
Dengue	1
Diphtheria	24
Influenza	3
Malaria	130
Measles	13
Mumps	11
Ophthalmia neonatorum	1
Pellagra	13

[2] Including paratyphoid fever

SMALLPOX IN TEXAS

The State Board of Health of Texas has compiled statistics showing that smallpox is increasing in that State. During the first seven months of 1924, 857 cases of smallpox were reported. During the same period of later years the number of cases was as follows: 1925, 1,228 cases; 1926, 1,668. Dr. H. O. Sappington, State health officer, urges health officers to use every means possible to secure vaccination of citizens in their respective localities.

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended August 14, 1926, 38 States reported 699 cases of diphtheria. For the week ended August 15, 1925, the same States reported 881 cases of this disease. Ninety-nine cities, situated in all parts of the country and having an aggregate population of more than 30,200,000, reported 402 cases of diphtheria for the week ended August 14, 1926. Last year for the corresponding week they reported 440 cases. The estimated expectancy for these cities was 534 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-six States reported 1,117 cases of measles for the week ended August 14, 1926, and 461 cases of this disease for the week ended August 15, 1925. Ninety-nine cities reported 332 cases of measles for the week this year, and 257 cases last year.

Poliomyelitis.—The health officers of 38 States reported 87 cases of poliomyelitis for the week ended August 14, 1926. The same States reported 289 cases for the week ended August 15, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-eight States—this year, 852 cases; last year, 654 cases; 99 cities—this year, 294 cases; last year, 325 cases; estimated expectancy, 240 cases.

Smallpox.—For the week ended August 14, 1926, 38 States reported 304 cases of smallpox. Last year for the corresponding week they reported 156 cases. Ninety-nine cities reported smallpox for the week as follows: 1926, 40 cases; 1925, 40 cases; estimated expectancy, 27 cases. One death from smallpox was reported by these cities for the week this year—at Portland, Oreg.

Typhoid fever.—One thousand one hundred and fifty-three cases of typhoid fever were reported for the week ended August 14, 1926, by 37 States. For the corresponding week of 1925, the same States reported 1,290 cases of this disease. Ninety-nine cities reported 204 cases of typhoid fever for the week this year and 264 cases for the corresponding week last year. The estimated expectancy for these cities was 229 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 94 cities with a population of nearly 29,700,000, as follows: 1926, 292 deaths; 1925, 347 deaths.

City reports for week ended August 14, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

[2] Dengue, 1 case at Miami, Fla.

The following table gives the rates per 100,000 population for 102 cities for the five-week period ended August 14, 1926, compared with those for a like period ended August 15, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 102 cities reporting cases had

an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, July 11 to August 14, 1926. Annual rates per 100,000 population. Compared with rates for the corresponding period of 1925 [1]

FOREIGN AND INSULAR

SMALLPOX ON VESSEL

Steamship from Glasgow, Scotland.—On July 17, 1926, a steamship arrived at Greenock, Scotland, from Canada, with history of a smallpox case removed from the vessel at a quarantine station on the vessel's outward journey from Glasgow to Canadian port. The vessel left Glasgow June 25 and the patient, a resident of Glasgow, was taken ill July 2, 1926. No history of smallpox in the patient's family was discovered, but it was found that four cases of chicken pox had occurred in the family and a small school epidemic of chicken pox had occurred in the district.

THE FAR EAST

Report for week ended July 31, 1926.—The following report for the week ended July 31, 1926, was transmitted by the far eastern bureau of the health section of the secretariat of the League of Nations, located at Singapore, to the headquarters at Geneva:

Maritime towns	Plague		Cholera		Smallpox	
	Cases	Deaths	Cases	Deaths	Cases	Deaths

[1] One infected rat has been found outside of the port area

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Iraq.—Basra.

British India—Negapatam, Chittagong, Cochin, Tuticorin, Vizagapatam.

Federated Malay States—Port Swettenham.

Straits Settlements.—Penang, Singapore.

Dutch East Indies—Batavia, Surabaya, Samarang, Cheribon, Belawan Deli, Palembang, Sabang, Makassar, Menado, Banjermasin, Balik-Papan, Tarakan, Padang, Samarinda.

Sarawak.—Kuching.
British North Borneo.—Sandakan, Jesselton, Kudat, Tawao.
Portuguese Timor.—Dilly.
Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.
French Indo-China.—Saigon and Cholon, Turane, Haiphong.
China.—Hongkong.
Formosa.—Keelung.
Kwantung.—Port Arthur, Dairen.
Japan.—Nagasaki, Moji, Kobe, Nugata, Tsuruga, Hakodate, Simonoseki.
Korea.—Chemulpo, Fusan.
Manchuria.—Antung, Mukden, Changchun, Harbin.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.
New Guinea.—Port Moresby.
New Zealand.—Auckland, Wellington, Christchurch, Invercargil, Dunedin.
New Caledonia.—Noumea.
Fiji.—Suva.
Hawaii.—Honolulu.

AFRICA

Egypt.—Port Said.
Anglo-Egyptian Sudan.—Port Sudan, Suakin.
Eritrea.—Massaua.
French Somaliland.—Jibuti.
British Somaliland.—Berbera.
Italian Somaliland.—Mogadiscio.
Kenya.—Mombasa.
Zanzibar.—Zanzibar.
Tanganyiki.—Dar-es-Salaam.
Seychelles.—Victoria.
Mauritius.—Port Louis.
Portuguese East Africa.—Mozambique, Beira, Lourenço-Marques.
Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from:

British India.—Calcutta.
Dutch East Indies.—Pontianak.
Madagascar.—Tamatave, Majunga.

CANADA

Communicable diseases, week ended August 14, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in seven Provinces of Canada for the week ended August 14, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Alberta	Total
Cerebrospinal fever			1	1		1		3
Influenza	10							10
Poliomyelitis				2				2
Smallpox				6		1		7
Typhoid fever	1		6	11	5		7	30

Communicable diseases—Ontario—July, 1926—Comparative.—During the month of July, 1926, communicable diseases were reported in the Province of Ontario, Canada, as follows:

Disease	July, 1926		July, 1925	
	Cases	Deaths	Cases	Deaths
Cerebrospinal meningitis	6	3		4
Chancroid	1		1	
Chicken pox	503		330	
Diphtheria	183	14	151	19
German measles	150		6	
Gonorrhea	131		144	
Influenza		10		5
Lethargic encephalitis	5	4		10
Measles	1,955	8	642	
Mumps	37		108	
Pneumonia		137		77
Poliomyelitis			4	
Scarlet fever	289	3	252	3
Smallpox	41		8	
Syphilis	118		65	
Tuberculosis	177	72	158	82
Typhoid fever	57		57	3
Whooping cough	325	3	345	9

Smallpox.—Smallpox was reported at 12 localities in the Province of Ontario, the greatest number being reported at MacTier and Peterboro, viz, 9 each; and at Belleville, with 6 cases; at Kingston and Parry Sound, 4 cases each were reported; at Ottawa and Richmond Township, 2 cases each; and at 5 localities, including Toronto, 1 case each.

CHINA

Morbidity—Mortality—Shanghai—July 1, 1925–June 30, 1926.—During the year ended June 30, 1926, there were reported at Shanghai China, 10,816 deaths among Chinese and 554 deaths in the foreign population. Cases of disease and causes of death were reported as follows:

Disease	Cases	Deaths	Disease	Cases	Deaths
Beriberi	6	34	Measles [1]		332
Cerebrospinal meningitis	2	6	Scarlet fever	106	556
Cholera	23	93	Smallpox	82	205
Diarrhea (acute) [1]		29	Tuberculosis [3]	52	996
Diphtheria	36	98	Typhoid fever [4]	88	347
Dysentery [2]	81	159	Typhus fever	1	1
Influenza		28			

[1] Not notifiable.
[2] Amebic, 38, bacillary, 43.
[3] All forms.
[4] Including 20 paratyphoid cases.

Population. Foreign, 38,046, Chinese, 1,098,065 Cases reported, foreign; deaths, Chinese.

Examination of rats.—During the same period, 28,114 rats were examined at Shanghai for plague infection. No plague-infected rats were found.

Arrivals from Canton subject to quarantine.—Under date of July 26, 1926, vessels arriving from Canton were declared subject to quarantine in the port of Shanghai on account of cholera.

CUBA

Communicable diseases—Habana—July, 1926.—During the month of July, 1926, communicable diseases were reported at Habana, Cuba, as follows:

Disease	New cases	Deaths	Remaining under treatment July 31, 1926	Disease	New cases	Deaths	Remaining under treatment July 31, 1926
Cerebrospinal meningitis	1	1		Measles	24	1	25
Chicken pox	2			Paratyphoid fever	3		2
Diphtheria	9	1		Scarlet fever	6		4
Malaria [1]	84	3	34	Typhoid fever [1]	57	12	43

[1] Many of these cases from the interior.

GREAT BRITAIN (SCOTLAND)

Further relative to typhus fever—Glasgow.[1]—Under date of August 3, 1926, seven cases of typhus fever were reported at Glasgow, Scotland. Later information showed that the occurrence was in persons belonging to the same family group and that previous illnesses had occurred in the family, one case about six weeks previous to the appearance of recognized typhus, and one, July 16, which ended fatally. To August 7, 1926, a total of nine cases of typhus was reported in this group.

JAMAICA

Smallpox (alastrim)—Other communicable diseases—June 27 to July 31, 1926.—During the period June 27 to July 31, 1926, 85 cases of smallpox (reported as alastrim) were reported in localities other than Kingston in the Island of Jamaica. Other communicable diseases were reported as follows:

Disease	Kingston	Other localities	Disease	Kingston	Other localities
Chicken pox	4	11	Tuberculosis	5	68
Leprosy	6	6	Typhoid fever	12	80
Puerperal fever		2	Yaws		15

JAPAN

Cholera—Yokohama—August 25, 1926.—The occurrence of a case of cholera at Yokohama, Japan, was reported August 25, 1926.

[1] Public Health Reports, Aug. 13, 1926, p. 1750, and Aug. 27, 1926, p. 1867.

LATVIA

Communicable diseases—June, 1926.—During the month of June, 1926, communicable diseases were reported in the Republic of Latvia as follows:

Disease	Cases	Disease	Cases
Cerebrospinal meningitis	6	Puerperal fever	1
Diphtheria	32	Rabies	4
Dysentery	20	Scarlet fever	199
Erysipelas	30	Tetanus	5
Leprosy	1	Trachoma	51
Measles	186	Typhoid fever	74
Mumps	13	Typhus fever	12
Paratyphoid fever	3	Whooping cough	50

Population, 1,850,000; estimated

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

...ED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst. Surg. Gen. B. J. LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912.

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

THE RADIOACTIVITY OF NATURAL WATERS

By W. D. Collins, Chemist in Charge, Quality of Water Division, United States Geological Survey

Every natural water is more or less radioactive, and therefore the recognition of the presence of a small amount of radioactive material in any spring water does not set that water apart from other natural waters.

Knowledge of the presence of radioactive substances in waters is comparatively recent. Therefore, the radioactivity has been seized as something to talk about and advertise as a remarkable and unique property of many waters which are no more unique in their radioactivity than they are in their wetness.

Physicians and others who have given thought to the subject have long recognized that, in general, much better results are obtained from the use of mineral waters at their sources than from the use of the same waters after they have been shipped in bottles. The common explanation has been that at resorts more water is taken, and at the same time the diet and other living conditions of the patient are better regulated than at home. Even without special medical attention at the resort there is usually rest, recreation, and freedom from the normal cares of life.

When radioactivity was first studied and it was found that many famous medicinal waters contained radium emanation, this fact was immediately taken as an explanation of the greater benefits derived from the use of the waters at their sources. The radium emanation is half gone in about 3.8 days after the water has been taken from its source and practically all gone within 30 days. So far the explanation seems reasonable. The first determinations of radioactivity of natural waters were nearly all made on samples from well-known springs. Later studies brought out great differences in the radioactivity of waters that seemed to produce identical beneficial effects and also showed radioactivity to be a universal property of natural water. As the use of radium emanation in the treatment of disease was developed, it appeared that the doses necessary to produce detectable effects could not be obtained by drinking any reasonable quantity of one of the naturally radioactive spring waters; of most waters it would be necessary to drink from 100 to 1,000 gallons a day.

In New and Nonofficial Remedies, 1925, page 308, it is stated that the Council on Pharmacy and Chemistry of the American

Medical Association will not accept any radium solution for internal use the dosage of which is less than 2 micrograms a day, or any radium emanation generator which yields less than 2 microcuries of emanation during each 24 hours.

To obtain the dose of 2 micrograms by drinking 1 gallon of water, which is considerably more than most people drink in a day, the radioactivity of the water would have to be about 500 millimicrocuries[1] per liter. As long ago as 1913 Lazarus, in his Handbuch der Radium-Biologie und-Therapie, stated (p. 200) that, in the use of waters having less than 20 millimicrocuries of radioactivity per liter, the radioactivity probably has no appreciable part in the beneficial effects obtained. It thus appears that the radioactivity should be between 20 and 500 millimicrocuries per liter in order to be considered at all as a factor in the use of a water as medicine, and that even within these limits the radioactivity is not likely to be the controlling factor.

In 1905 Boltwood[2] reported the radioactivity of waters from a group of 44 springs which have been used medicinally for bathing or drinking. The radioactivity ranged from 0.016 to 8.8 millimicrocuries per liter and only two had over 2.5 millimicrocuries per liter. Half of the results were between 0.1 and 0.5. Schlundt and Moore[3] found less than 0.5 millimicrocurie per liter for 40 out of 88 springs in Yellowstone National Park; the maximum reported was 2.68 millimicrocuries per liter.

Measurements by the writer quoted by Skinner and Sale[4] in a discussion of the radioactivity of miscellaneous waters examined in the Bureau of Chemistry gave results ranging from 0.007 to 1.1 millimicrocuries per liter for 15 samples of spring waters collected in 1911, 1912, and 1914 in Virginia, Wisconsin, and Massachusetts. Some of these samples were taken from widely known springs.

The text by Lazarus noted above contains an article by Sommer which gives results of measurement of radioactivity of 422 waters from springs in Germany. The radioactivity of 72 per cent of these waters was reported as less than 2.5 millimicrocuries per liter.

Moore and Whittemore[5] measured the radioactivity of 14 waters at Saratoga Springs, N. Y., and found from 0.039 to 0.88 millimicrocurie per liter. Satterly and Elworthy[6] report the radioactivity of waters from 23 wells and 47 springs in Canada. The results range from

---

[1] A millimicrocurie is the radioactivity corresponding to one-billionth of a gram of radium (0.000000001 gram). This unit is used in discussions of the radioactivity of natural waters because results expressed in it are numbers of moderate size. Some reports have been made in units of one-tenth to one-thousandth of a millimicrocurie, but all the results quoted in the present discussion have been converted to millimicrocuries.

1

0.0014 to 0.176 millimicrocurie per liter for the well waters and from 0.0112 to 0.64 for the spring waters.

Measurements by O. C Lester of the radioactivity of 178 mineral waters of Colorado are given in Bulletin 11 of the State Geological Survey, published in 1920. The results range from "none" to 30 5 millimicrocuries per liter. The report "none" signifies only that no radioactivity was detected with the apparatus used and does not indicate the complete absence of radioactivity. Of the waters with measurable radioactivity 85 per cent had less than 2 5 millimicrocuries per liter, 14 per cent from 2.5 to 5, and 6 per cent from 5 to 30.

Other results quoted by the authors cited above serve to show the almost universal radioactivity of natural waters as they occur in the ground and the exceedingly small quantities of radioactivity in even the most radioactive of these waters when compared with the quantities which those who have studied the subject consider necessary to produce any therapeutic effect

The best available evidence based on scientific studies of the treatment of disease with radium emanation, on measurements of radioactivity of natural spring waters, and on the reported uses of the spring waters, leads to the conclusion that, up to this time, it has not been shown that the small amounts of radioactivity found in natural waters have any effect on the medicinal value of the waters.

THE PHYSIOLOGICAL EFFECTS OF CURRENTS OF VERY HIGH FREQUENCY (135,000,000 TO 8,300,000 CYCLES PER SECOND)

By J W SCHERESCHEWSKY, Surgeon, United States Public Health Service

This paper reports the results of studies of the effects upon small laboratory animals (mice) of electrical oscillations of very high frequency generated by a vacuum tube oscillator.

The modern development of the vacuum tube oscillator and associated circuits permits the generation of continuous wave currents of relatively pure wave form of very high frequency, sharply emitted at the frequency to which the circuit is tuned. This is not the case in the usual type of high frequency apparatus used for therapeutic purposes. Here, the oscillations are produced by condenser discharge across a spark gap. The oscillations produced in this way have a large decrement, the wave form is impure, giving rise to many harmonics; the emitted wave is broad, and consistent operation at the frequencies worked with in the studies here reported is difficult to obtain. Moreover, the oscillations generated are in the form of discontinuous trains separated by a period during which the upbuilding of energy for the next train occurs.

The physiological effects of high frequency currents generated by the vacuum tube oscillator appear to have been but little investigated.

The only reference found by a search through the literature was a report by Gosset, Gutmann, Lakhovsky, and Magrou [1] on the effects of very high frequency radiation emitted by a vacuum tube oscillator upon plant tumors caused in the geranium by *Bacterium tumefaciens*.

The authors report that three geranium plants, bearing tumors caused by inoculation with the above-mentioned organism, were exposed to radiations emitted by a vacuum-tube oscillator at a frequency said to be about 150,000,000 cycles per second. One plant was given 2 exposures of three hours on consecutive days, one plant 3, and one plant 11 such exposures. After 16 days from the first exposure, the tumors, after growing in the interval, began suddenly to necrose. The necrotic process was said to be complete in about 15 days, so that the tumor could be detached by slight traction. In 16 control plants the tumors grew rapidly to enormous size and recurred after surgical excision. Details, however, as to the apparatus and method of exposure are lacking.

In the studies here reported the first step was a study of oscillators which might generate oscillations of sufficiently high frequency and the development of suitable auxilliary circuits in which the effects of such currents on small laboratory animals (mice) might be investigated.

At this point it is desired to express grateful acknowledgment to Prof. George W. Pierce and E. L. Chaffee, of the Cruft High Tension Laboratory of Harvard University, for permitting the use of the facilities of the Cruft High Tension Laboratory in the preliminary work and for much helpful advice; also to Mr. M. L. Dow and Mr. F. H. Drake, of the same laboratory, for collaboration, valuable assistance, and advice in the working-out, construction, and setting-up of apparatus and in making preliminary runs and tests.

Further grateful acknowledtment is made to Prof. M. J. Rosenau, of the Department of Preventive Medicine and Hygiene of the Harvard Medical School, for the use of the facilities of his department in the subsequent work. It is also desired to thank the General Electric Co. for furnishing three special vacuum tubes of low internal capacity.

Description of Apparatus

Vacuum tube oscillator. After considerable preliminary work in testing the suitability of various types of oscillators, the following types of circuit were settled upon as satisfactory:

For the generation of the highest frequency currents employed, (i. e., from 200,000,000 cycles to 60,000,000 cycles per second) the type of oscillator described by Huxford [2] was found excellently

adapted. In the design of circuits intended to oscillate at these high frequencies, the interelectrode capacity of the tube, negligible at low frequencies, becomes an important limiting factor on the frequency of the oscillations generated. In Huxford's circuit the capacity formed by the tube elements is in series with the variable tuning capacity. Because of well-known physical considerations, this has the effect of reducing the minimum capacity at which the oscillating circuit may be resonated, and thus permits the generation of frequencies

higher than would be possible with a tube having a given interelectrode capacity, were this capacity in shunt with the tuning capacity as is the case, for instance, in the well-known Hartley circuit.

Two oscillators of the type described by Huxford were constructed, one having a range of from about 200,000,000 cycles to 85,000,000 cycles and the other with a range of 150,000,000 cycles to 60,000,000 cycles per second. Figure 1 shows the circuit network and the accompanying photographs show the appearance of the oscillators,

Reference to the diagram and photograph of oscillator No. 1 (Pl. I) shows that the tuning inductance consists essentially of two parallel brass rods 21 centimeters long, 4.7 millimeters in diameter, and spaced 5 centimeters, supported at each end by vertical bakelite strips. At the vacuum tube end the upper rod is connected to the grid, while the lower is connected to the plate of the tube. This lower rod is revolubly mounted and serves as a support for the rotary plate of the tuning condenser which is mounted on the rod by means of a sleeve and set-screw, so that it may be moved and fixed at any point on the lower rod. The upper rod, which is not revoluble, carries the stator portion of the tuning condenser. This is suspended from a small brass block, bored to a sliding fit upon the upper rod and secured by a set-screw so that it may be appropriately located with respect to the rotary plate. The stator portion of the condenser consists of two plates spaced 3.1 millimeters from each other, with a radius of 4.7 centimeters The rotary plate has a radius of 3.75 centimeters.

This arrangement of the tuning condenser which permits it to be slid to different sites along the rods is an important means of varying the oscillator frequency, as the range obtained by varying the condenser alone, at any one position on the rods is rather narrow. To get the benefit of the full range of frequencies of which the oscillator is capable, it is necessary to alter the value of the inductance in the oscillating circuit. This is done by sliding the rotor and stator portions of the condenser to different sites along the rods, the inductance in the circuit being a maximum when the condenser is slid as far away from the tube as possible. The farther ends of the rods are connected through suitable choke-coils to the filament and to the plate battery, respectively, the upper rod being connected to the negative filament through a variable resistance. The resistance used was a Bradley, variable between the values of 10,000 and 200,000 ohms. In the circuit, as described by Huxford, no resistance was employed; but in this instance its use appeared to add stability and efficiency, besides, because of its biasing action, reducing consumption of plate current and undue heating of the plate.

As shown in the diagram, the oscillating current was confined to the oscillating circuit by the use of suitable choke coils. These were four in number and were located, one in each leg of the filament, one at the outer end of the lower rod between it and the plate supply, and one at the outer end of the upper rod between this and the grid-biassing resistance. In oscillator No. 1 these choke coils consisted of 23 turns of No. 20 D. C. C. wire wound in a spiral 1.25 centimeters in diameter, each turn being slightly spaced from the next. They were readily made by winding the required number of turns tightly around a ⅛-inch rod and then slipping them off, the small diameter of the coil and the natural stiffness of the wire rendering

the coils self-supporting. While 23 turn coils were used and found to work well, this number is by no means critical. It could probably be varied several turns in either direction without changing results.

Oscillator No. 2 was a duplicate, in constructional details, of the first oscillator, except for larger dimensions. The rods were 38 centimeters long and spaced 11.5 centimeters instead of 5 centimeters. The tuning condenser, too, was larger, having five instead of three plates. Because of the wider spacing of the rods, it was necessary to make the brass block which carried the stator of the condenser considerably longer than in the smaller model

It will be noted, from the photograph, that, in the smaller oscillator, no socket for the tube was used, the tube being mounted by inserting the base, until stopped by the pin, in a hole of proper diameter, in a horizontally mounted bakelite strip. The plate, grid, and filament leads were then soldered directly to their respective tube prongs. This was done to avoid introducing unnecessary capacity in the circuit through the use of a socket. In the other oscillators, however, where lower frequencies were generated, this precaution was needless; consequently, for the sake of convenience, a socket was employed.

The vacuum tube used for the generation of high-frequency current was the UX 210. This tube has a thoriated filament, is rated at 7.5 watts, is used with a maximum filament current of 1.25 amperes at 7.5 volts. The plate potential employed was 400 volts, furnished by a suitable number of 6,000 m. a.-hour lead storage-cells.

This tube was found to oscillate vigorously in the circuit just described up to a frequency of 158,000,000 cycles. At this point the internal capacity of the tube and the inductance of its leads were so great that oscillations of higher frequency could not be obtained. However, by the use of the special tubes (shown in Plate II) having a low internal capacity, which were obtained from the research laboratories of the General Electric Co., with the smaller oscillator it was possible to generate effective oscillations of a frequency around 200,000,000 cycles per second, and feebler ones of possibly 230,000,000 cycles.

As shown by the photograph, this tube has the filament and plate leads brought out at the lower end of the tube while the grid lead is brought out at the top. This reduces the capacity between leads within the tube which, in the ordinary type of mounting, may be several micromicrofarads.

Measurements of the internal capacity of this tube made at 1,000 cycles on the Cruft Laboratory capacity bridge showed this to be between 3 and 4 micromicrofarads, less than one-half that of a standard UV 202, 5-watt tube.

While the tubes, when received, were provided with bases, these were removed, by heating, before use so as to reduce the tube capacity to a minimum.

It was found that the generation of these high frequencies was very hard on the tubes, it being necessary, in order to secure adequate output, to increase the filament and plate currents considerably beyond the normal standard. This resulted in burn-outs, cracking of seals, and, in the case of the UX 210 tube, of depletion of electron emission beyond the possibility of reactivation.

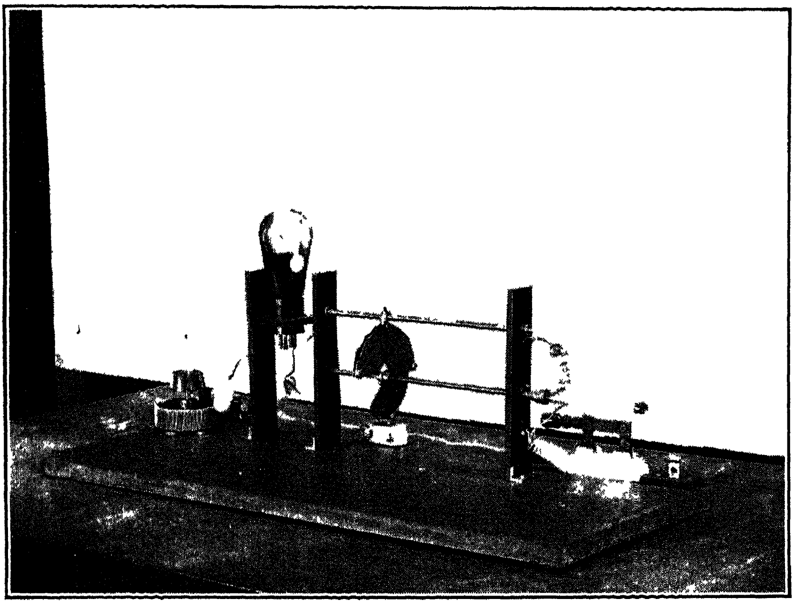
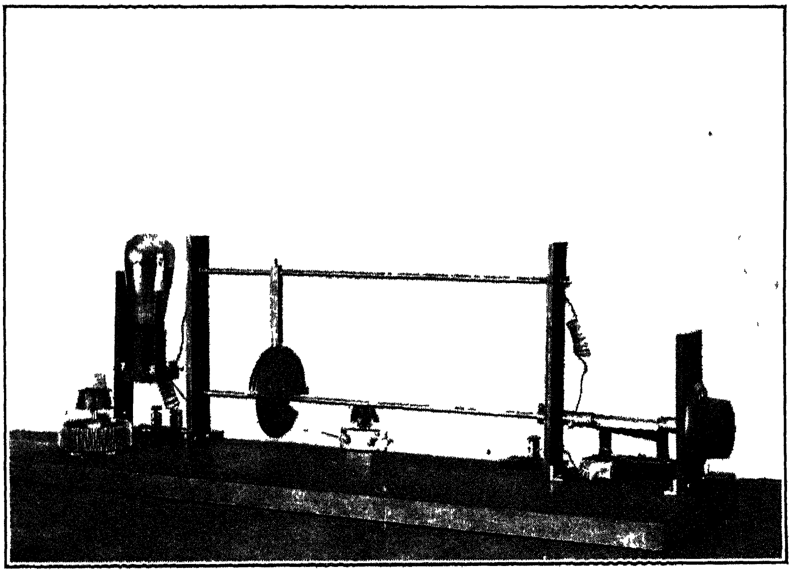
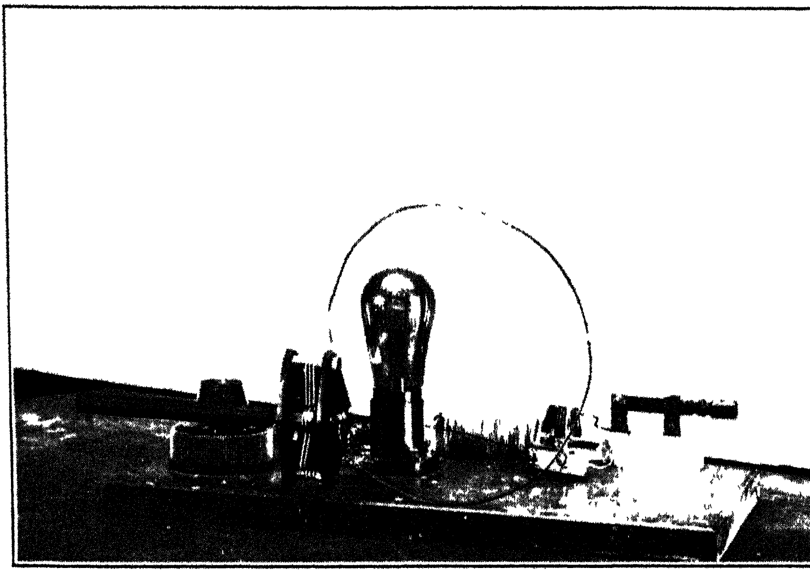
For frequencies of 60,000,000 cycles per second and less it was no longer found necessary to use the type of oscillator just described, which, though reliable and stable in operation, nevertheless, because of limited range was not as well suited to the exploration of the lower frequencies, as the ever useful and efficient Hartley circuit. Consequently, for these lower frequencies, the latter circuit with parallel plate feed, through a choke coil, was employed as shown in Figure 2 and the accompanying photograph.



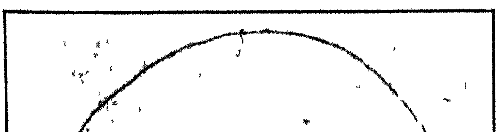
Oscillator No 1 (Huxford circuit) Range 230,000,000 to 85,000,000 cycles



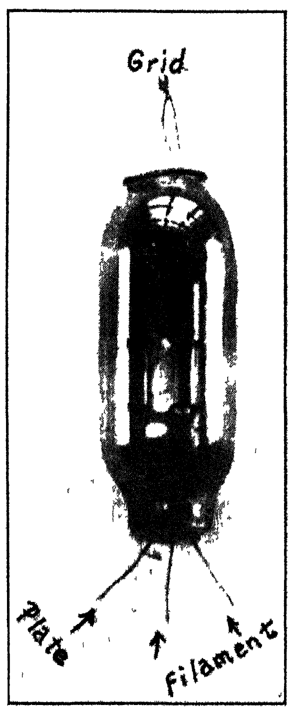
Oscillator No 2 (Huxford circuit) Range 150,000,000 to 60,000,000 cycles



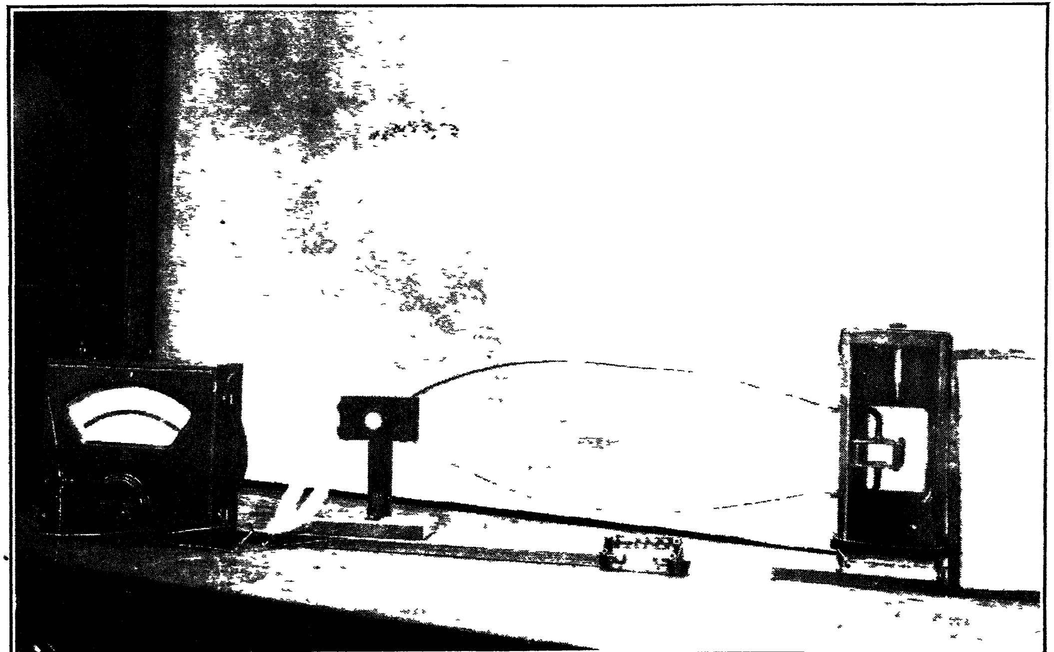
Oscillator No 3 (Hartley circuit). Range 50,000,000 to 23,000,000 cycles



Oscillator No. 3 (Hartley circuit). Range 20,000,000 to 7,250,000 cycles



Special 5-watt vacuum tube with low internal capacity



Auxiliary-coupled circuit showing mouse holder, thermocouple, and microammeter

For the inductance, single turn loops of No. 14 to No. 4 wire were used according to size and the need for rigidity. These loops, as shown in the photograph, were supported on the tuning condenser (a low-priced 5-plate affair with bakelite end plates which was found to function as satisfactorily as one of the most expensive "low loss" construction).

For frequencies below 12,000,000 cycles, however, a high-grade 17-plate condenser was used. The plate-blocking condenser, a Dubilier micadon, had the value of .00025 mfds. The filament return was taken off the mid-point of the tuning inductance, the connection to the negative filament being made, as in the case of the other oscillators, through a variable Bradley resistance, the usual resistance values used being from 10,000 to 15,000 ohms.

Choke coils of several sizes were inserted in the plate feed, larger choke coils being used for the lower frequencies. As in the case of the oscillators previously described, these consisted of a self-supporting spiral of No. 18 or No. 20 D. C C. wire, the number of turns varying from 23 to 65 or 70 and the diameter from 2.5 to 4 centimeters, the turns being spaced about the diameter of the wire.

With this type of oscillator, simply by varying the diameter of the single turn used as the inductance, with the 5-plate condenser it was possible to go from 66,000,000 cycles per second (using a 6-centimeter loop) to 10,000,000 cycles per second (using a turn of No. 4 copper wire 76 centimeters in diameter). With a single turn loop 32 centimeters in diameter tuned by a .00035 mfd. condenser, frequencies as low as 7,500,000 cycles could be readily generated.

In all the oscillators the filament temperature was controlled by a 2-ohm rheostat. A Weston ammeter in the filament circuit and a Weston 0-300 milliammeter in the plate circuit indicated the filament and plate currents, respectively. The latter instrument was placed in the negative plate-battery lead and was protected by the insertion of a short strip of ¼-ampere fuse wire.

It was generally found that, for adequate output, the necessary plate current was considerably greater at the higher than at the lower frequencies. At the highest frequencies, during some of the runs, plate current readings of from 100–120 milliamperes were not unusual, but at the lower frequencies from 50 to 80 milliamperes was the usual value.

Frequency determination.—For the purpose of ascertaining the frequency at which the oscillator was operating, use was made of a Lecher parallel wire system. This consisted of two No. 12 parallel copper wires 7.5 centimeters apart and 11 meters long, stretched from standards 20 centimeters above the level of the workbench. Turnbuckles at one end of the wire system served to tighten the wires.

The slider was a rectangular piece of 22-gauge brass plate 12.5 by 8 centimeters, provided with two parallel slots 7 centimeters long and 7.5 centimeters apart to enable it to engage the wires. Supporting sliders of bakelite, grooved to fit the wire and attached front and rear steadied the slider plate, enabling it to travel smoothly. A waxed string passing over pulleys attached to the standards allowed the slider to be moved to any position from the operator's location. A plumb bob suspended by a waxed thread from the slider indicated its position with respect to a wave-length scale laid out on the workbench beneath. Resonance of the wire system with the oscillator frequency was indicated by a Weston thermogalvanometer connected across the oscillator end of the wires.

In a system of this character, as is well known, standing waves are formed on the parallel wire system in a series one-half wave in length between nodes. If the slider is placed at one of these nodes the wave will travel along the wires to the slider and be reflected back, the total distance traveled being equal to the distance between wave crests, and therefore corresponding to the wave length. When the slider is located in this fashion at a node the meter will show the maximum deflection.

The system is readily calibrated by setting the oscillator at some frequency sufficiently high to permit the development of several successive nodes on the wire system, moving the slider to each of these points in succession and measuring the interval between them; and averaging the measurements which will be found to differ from each other by less than a centimeter. In this way orientation points on the wave-length scale are readily located from which the wave-length scale may be laid out, the wave-length measured, and hence the frequency determined.

Although, owing to the capacity between the wires and also to the surface of the bench, a slight error is introduced, so that the apparent frequency is slightly higher than the actual, still this method of measuring the wave length, and consequently the frequency, is remarkedly accurate, the error probably being one-half of 1 per cent or less.

Since available space permitted a wire system only 11 meters long, wave lengths only up to approximately 21 meters, or frequencies somewhat less than 15,000,000 cycles, could be directly measured. For lower frequencies a wave meter was employed. This consisted of a loop 32 centimeters in diameter made of ⅛-inch brass rod and a high grade .00035 mfd. condenser in series therewith, resonance being indicated either by the lighting of a low-resistance flash lamp bulb in series with the loop and condenser, or by observing the deflection of the plate-milliammeter needle of the oscillator at the reso-

nance point. This latter method was preferred because of the sharpness of the reaction.

This wave meter was calibrated at the Cruft High Tension Laboratory by comparison with the Cruft Laboratory precision wavemeter for this range of frequencies which, in turn, had been calibrated against a quartz-crystal controlled oscillator [3]

Utilization of oscillator output.—In studying the effects of the oscillator output at various frequencies upon laboratory animals it would obviously be inexpedient to make use of any conductive arrangement, as the constants of the oscillating system would thereby be seriously disturbed. In these studies, therefore, the effects of of these high frequency currents upon animals were investigated by the use of a tuned circuit which was inductively coupled to the oscillator.

As shown in the circuit diagram (fig. 3) and photograph (Pl. III), this tuned circuit consisted of a single-turn wire loop, having a thermocouple (to measure the current) inserted at its mid-point and a capac-

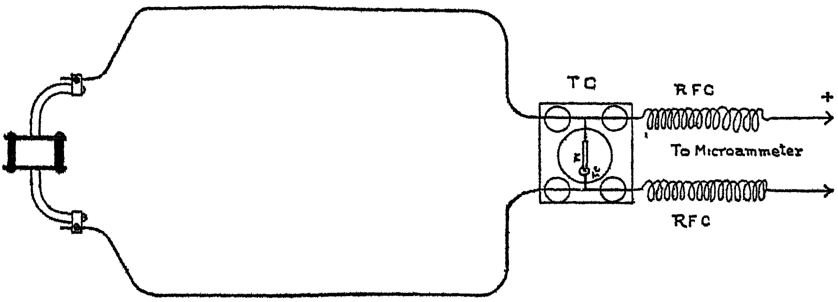


FIG 3.—Auxiliary-tuned circuit and thermocouple

ity consisting of a pair of rectangular brass plates 7.4 by 4.3 centimeters, 2 centimeters apart. The separation of the plates was rigidly fixed by means of four ¼-inch hard-rubber posts each 2 centimeters long at each corner of the plates. Since it was determined to study the action of the electrostatic field between the condenser plates, to avoid any conductive transfer of energy the inner surface of each condenser plate was covered with a celluloid sheet 0.004 inch in thickness. The subject for experimentation (a mouse) was placed in a small celluloid box with perforated sides (see Pl. III) and inserted between the condenser plates where it fitted snugly.

The dimensions of the condenser given above were not the result of any calculation, but were determined by the size of the celluloid box which was designed to hold a 20–22 gram mouse comfortably without, at the same time, permitting it to turn and twist too freely. The box consisted of two pieces of stout celluloid for the top and bottom, held

[3] See Piezoelectric Crystal Resonators and Crystal Oscillators Applied to the Precision Calibration of Wave-meters. By George W. Pierce. Proceedings of the American Academy of Arts and Sciences, vol. 59, No. 4.

apart by ¼-inch hard-rubber posts to which they were secured by short screws in holes tapped at each end of the posts. The sides of the box were covered in with strips of stout celluloid perforated with numerous ⅛-inch holes for ventilation, glued to the hard-rubber posts by means of cellulose varnish.

While mice of from 19–22 grams in weight fitted snugly in the box, so that they could indulge in but moderate twisting and turning about, still, confinement in the box was apparently not uncomfortable per se, as mice frequently went to sleep when undisturbed. Confinement in the box of several hours' duration was without effect upon mice.

The capacity of the condenser without mouse or mouse holder was found to be 1.1 micromicrofarads. Putting the empty mouse holder in place increased the capacity to 8.1 micromicrofarads. With a 20-gram mouse in the holder the capacity increased to 16.1 micromicrofarads. These measurements were made at 1,000 cycles on the Cruft Laboratory capacity bridge. The capacity of the condenser with mouse holder and mouse was, therefore, about four times greater than the capacity with air alone as the dielectric.

Current measurement.—The amount of oscillating current induced in the auxiliary-tuned circuit was measured by means of a platinum-tellurium thermocouple which was constructed for the writer by Mr. F. H. Drake, of Cruft Laboratory. This consisted of a bit of tellurium supported upon a piece of 22-gauge nickel wire to which it was fused. This in turn was soldered to a short piece of No. 18 copper wire. A piece of 7-mil. platinum wire was rolled to a ribbon approximately 1 mil. in thickness. A piece of this about 1 centimeter long was soldered at one end to a short piece of 18-gauge copper wire, while the other end was made somewhat pointed by means of shears. The pieces of copper wire to which, respectively, the platinum ribbon and the tellurium were attached were mounted vertically, through holes in which they were a tight fit, on a stout piece of bakelite at such distance apart that the pointed end of the platinum ribbon fell naturally about on the center of the tellurium fragment. Upon passing direct current regulated by a variable resistance from a 6-volt storage battery, the platinum ribbon was heated to redness. The tellurium fused at the point of contact and thus became solidly welded to the platinum ribbon. A cap fitted over the thermocouple protected it from the effect of air currents. The circuit diagram of the thermocouple is shown in Figure 3.

It will be seen that the thermocouple is connected across two conductors, two ends of which form part of the auxiliary-tuned circuit, the other ends being connected through choke coils to the plus and minus posts of a Rawson microammeter. This instrument had a resistance of 52 ohms and a full scale reading of 120 microamperes.

The resistance of the thermocouple was found to be 0.3 ohms at 1,000 cycles.

The thermocouple was calibrated on 60-cycle A C. by noting the scale reading of the microammeter for various current values as determined by the voltage drop across standard resistances measured by a Rawson vacuum thermocouple voltmeter The full scale read-

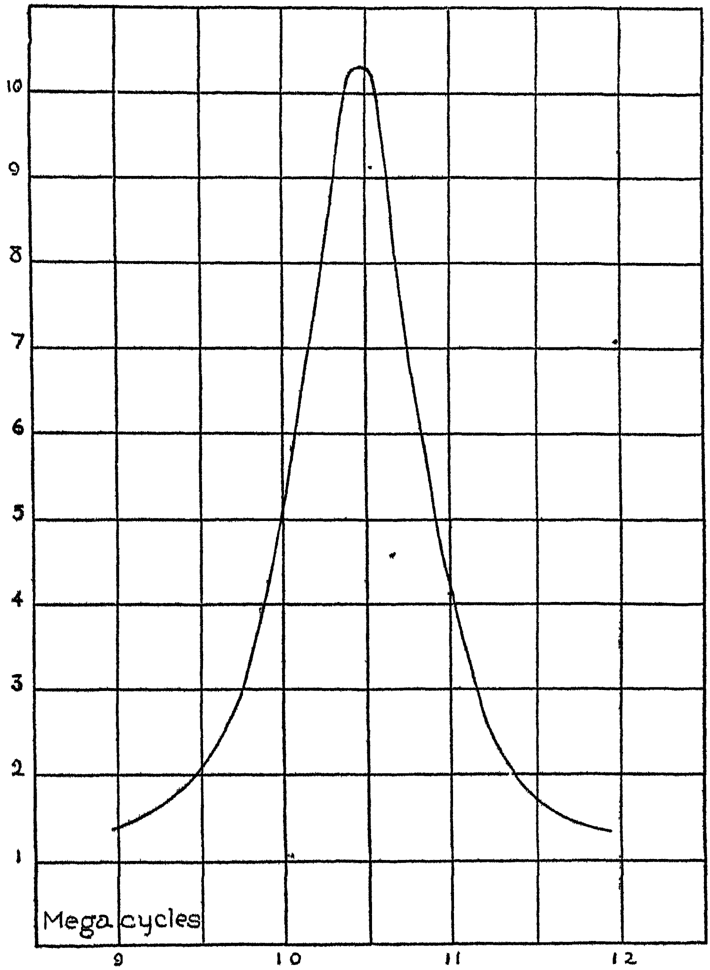

FIG 4.—Resonance curve of auxiliary-tuned circuit with 20-gram mouse. Peak at 10.42 megacycles

ing of 120 on the microammeter corresponded to 0.61 amperes. At 5 on the scale the current was 0.139 amperes.

The calibration of this thermocouple was checked at frequent intervals throughout the study and remained unchanged.

Tuning the auxiliary circuit.—Since the output of the oscillator was applied to the experimental animals, by means of the current

induced in the auxiliary circuit placed in inductive relation to the oscillator the first step in any experiment was, of course, to tune the coupled circuit to the oscillator frequency so that the current in this circuit should be a maximum. To do this, a mouse immediately after death by gas was placed in the celluloid box and inserted between the condenser plates. A loop was then formed by joining with

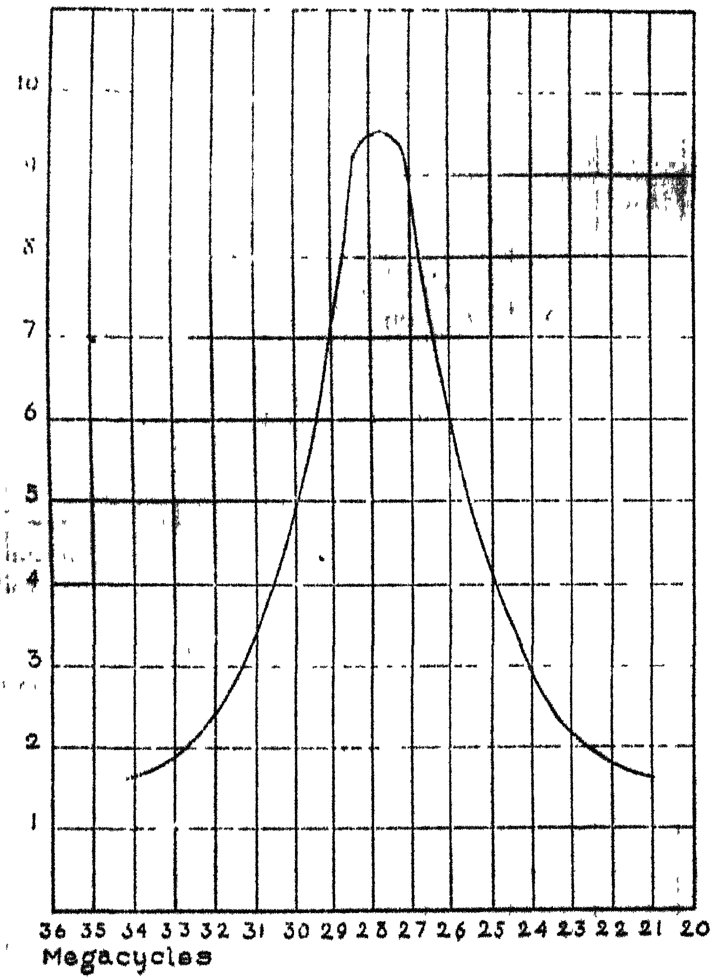

FIG. 5. Resonance curve of auxiliary-tuned circuit with 20-gram mouse. Peak, 28.4 to 27.2 megacycles

two pieces of stiff wire the high frequency terminals of the thermocouple with the corresponding condenser terminals. As a first approximation the length of wire was arbitrarily chosen at a value which experience showed to be about the length desired. Then by starting the oscillator and varying its tuning condenser until maximum current was flowing in the coupled circuit, upon determining the fre-

quency an idea could readily be had of how closely the auxiliary circuit was tuned to the frequency it was desired to study. With this information it was easy to add or to subtract wire from the auxiliary circuit as required, fine adjustment being finally made at the condenser terminals by loosening the set screws which held the wire in place in holes in the arms supporting the condenser and adjusting the length of the inductance by pushing the wires in or pulling them out of the holes The graphs (Figs 4 and 5) of the resonance peak of the tuned auxiliary circuit measured at 10,400,000 cycles, and at 28,400,000 cycles, give a good idea of the type of resonance obtained in this circuit

It will be noted that the circuit tunes more sharply at the lower frequency. In this case the peak of the resonance curve is about 180,000 cycles broad, while, at the higher frequency, the breadth of the peak is about 1,200,000 cycles.

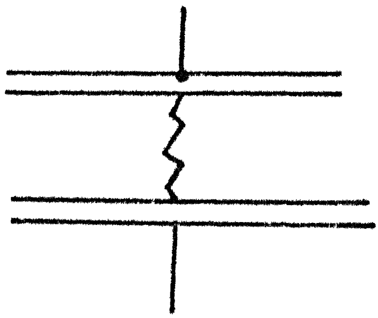
We may, therefore, conclude, since the tuning of the auxiliary circuit is rather broad, that this circuit presents considerable resistance. Hence, only approximate accuracy is necessary in setting the auxiliary circuit to resonance as the current flowing through it, when tuned to somewhere near the oscillator frequency, is ample for experimental purposes.

Effects of Exposure on Laboratory Animals

It will be noted in the auxiliary circuit just described that the experimental animal, insulated in a box of nonconducting material, is placed in the field between the plates of the condenser while the coupled circuit is excited by the oscillator at some particular frequency. Consequently, no free electrons from the external metallic parts of the circuit can enter, nor can they flow out from the body of the experimental animal. The mouse, however, is subjected to a displacement current, in which electrons in the molecules of the body cells will, according to their state of freedom, either pass from molecule to molecule, first in one and then the other direction or, if bound, are stressed in a direction the polarity of which alternates at the oscillator frequency.

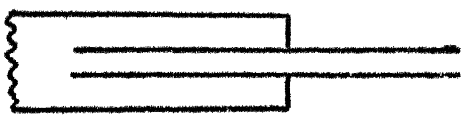
The equivalent electric circuit presents at least two possibilities. The first and more probable possibility is that the system may be regarded as two condensers in series connected by a resistance, the first condenser being formed by one plate of the condenser and the body surface of the mouse, in close proximity to it, the intervening celluloid acting as a dielectric. The second condenser is formed, in

similar fashion, by the lower surface of the body, the intervening tissues acting as the connecting resistance thus:



That this equivalent circuit is probable is shown by the fact that we can readily substitute in place of the mouse two metallic plates connected with each other and spaced far enough apart to fit snugly against the top and bottom of the box. It was determined experimentally that two rectangular copper plates each 2.5 by 2 centimeters and spaced 2 centimeters by a connecting copper strip furnished an electrical equivalent for a mouse. If the coupled circuit were tuned to the oscillator frequency with this arrangement in the box, it was found to be approximately in tune if a mouse were substituted. However, the coupled circuit with the substitute in place had naturally a much lower resistance than with a mouse, so that the current registered for a given filament temperature was considerably higher.

Another possibility is that the mouse's body acts in the circuit as a dielectric of poor quality. In this case the electric equivalent would be a condenser shunted by a resistance as shown below.



It has already been mentioned that the insertion of the mouse holder containing a 20 gram mouse between the condenser plates increased the capacity about four times. The effect of the presence of the mouse holder and mouse on the tuning of the circuit is well shown in the following way. When the auxiliary circuit, with the mouse in place, is tuned to the oscillator's frequency, if the mouse holder and mouse are then removed the needle of the microammeter, indicating the current in the tuned circuit, drops to zero. If the oscillator be tuned to resonance with the circuit in this condition, the frequency will be found at a point considerably higher.

In this case, as might be expected, with a perfect dielectric, as air, filling the space between the condenser plates, the resistance of the

circuit is lower, so that the resonance peak is sharper and the current flowing greater for a given oscillator output.

While it may well be that the electrical behavior of the mouse in the circuit partakes of both modes of action just described, still, on the whole, the first state of affairs described seems the more likely.

Effects upon laboratory animals.—Exposure of small laboratory animals, such as white mice, in the manner described, to the rapidly oscillating field between the condenser plates of the auxiliary tuned circuit, causes death usually in a few minutes if the current value be sufficiently great.

The symptoms observed are, in general, as follows: For a short, variable time the mouse is quiescent. This is followed by agitation increasing with the length of exposure. The ears, tail, and paws turn a bright pink which, in many instances, becomes livid or cyanotic as the exposure is prolonged. There is salivation, the nasal secretion is increased; the head and under parts of the body become wet and bedraggled; the paws are covered with beads of moisture. After a variable time convulsions accompanied by convulsive winking take place, dyspnea sets in, and finally respiration ceases. In males there is usually considerable swelling of the genitalia. The heart, however, continues to beat for a little while after respiration ceases.

In the great majority of instances the body of the mouse appears distinctly warm to the hand, and if the rectal temperature be taken immediately after death considerable elevation in the body temperature is found to have taken place, the temperature varying from 42.2° to 43.1° and even 44° C. However, this is not always the case, as death was repeatedly observed to occur in the usual time, and yet the elevation of the body temperature was only moderate, in one instance the rectal temperature not exceeding 39.2° C., a temperature which is not infrequently observed in apparently normal mice. However, in the majority of instances the exposure has caused considerable elevation of the body temperature and we may infer that the primary fatal effect observed consists in raising the body temperature to a degree incompatible with life.

Since the rectal temperature of a normal mouse, according to the temperature of the environment, may be anything from less than 37° to about 39° C., the exposure has brought an increase of the body temperature of anywhere from 5° to 6° C.

In the case of mice, however, which had been killed by exposure to carbon monoxide gas, and then immediately exposed in the coupled circuit, the heating effect was far less pronounced. In dead mice it was found, using the same current and time of exposure necessary to kill living mice at that particular frequency, that the

rise in the body temperature of the dead mouse was of a much lower order, amounting to but 0 7° to 1° C. In many instances there was no gain, and in others a loss was recorded.

This would suggest that the heating effect is different from the diathermic effect observed at the lower frequencies used for therapeutic purposes, as by the use of high-frequency current in diathermic apparatus it is easy to raise the temperature of dead tissues well above the point at which albumen coagulates.

However, at certain frequencies considerable heating effect was observed even in dead mice Thus, at 6 6 meters, or a frequency of 45,000,000 cycles, 3 dead mice, as the result of exposure lasting 8.5 minutes, showed gains in the rectal temperature of 2.33° 3.6° and 4.4° C., respectively.

Sequelæ of exposure to sublethal doses.—Apart from the acute symptoms previously mentioned exposure to these high-frequency currents may cause destruction of tissue. After sublethal exposures, in many instances, small hemorrhagic areas may be observed along the course of blood vessels of the ears. In the course of 48 hours the ears become necrotic and drop off. The tail also often presents numerous ecchymotic areas. It may subsequently become affected with dry gangrene and drop off. In other instances areas of alopecia develop, particularly in the supra-orbital region or at the tip of the snout. In one instance a panophthalmitis developed with subsequent loss of vision.

Effects of change in frequency.—In preliminary observations it soon became evident that the effects of exposure to different frequencies was not the same, a current of constant value proving more lethal at some frequencies than at others Furthermore, the change in lethal effect did not appear to bear any simple relation to change in frequency, as one would be led to expect, so it was determined to study the changes, if any, in the lethality of a constant current as the frequency changed. Since part, at least, of the effect of the exposure was due to increase in the body temperature which, in turn, might be modified by changing external temperature conditions, it was evident that, to avoid serious error, the observations must all be made under substantially constant meteorological conditions.

The standard conditions of temperature and humidity at which to conduct the experiments were arbitrarily fixed at 24° C. and 40 to 42 per cent relative humidity, as these represented a fair average of the atmospheric conditions at which preliminary observations were made.

To secure these conditions, the apparatus depicted in Figure 6 was set up. As will be seen from the diagram, it consisted of the following parts:

The condenser, in the field of which the mouse was exposed, was mounted in a wooden box 22 by 10 by 9.5 centimeters outside dimen-

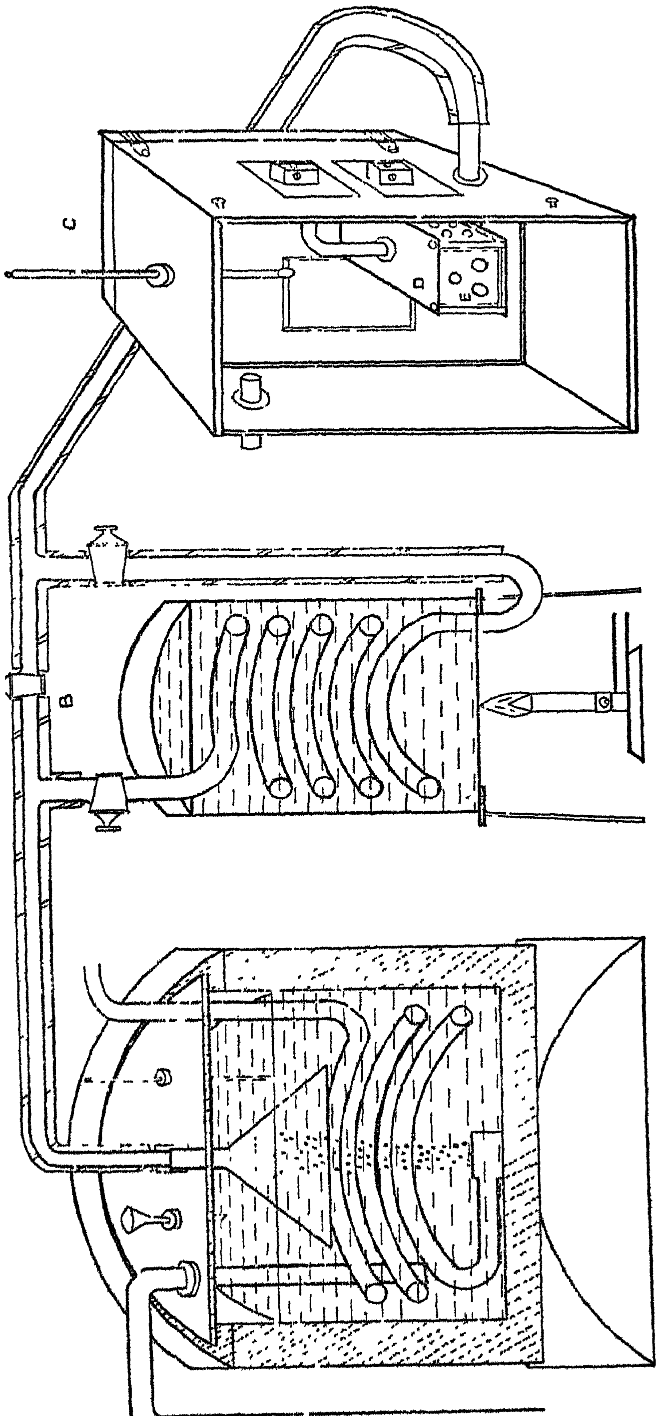


Fig 6.—Constant temperature and humidity apparatus A, Humidifier, B, Hot-water bath, C, Box containing condenser, D, Condenser, E, Mouse holder

sions. The front and back sides of the box, provided with celluloid windows for observation, were removable and were held in place by stout rubber bands To secure a close fit, the inner side of each was fitted with a rubber gasket 1 centimeter wide which bore against the edges of the box.

Air taken from the laboratory compressed-air supply was first cooled and partly saturated by bubbling through water in a large wash bottle, which itself was cooled to approximately 10° C. by immersion in water of that temperature. The air issuing from the wash bottle was piped to a copper coil inside a large container packed in sawdust and filled with water which was kept at a constant temperature of 10° C. From the copper coil the air issued in a stream of fine bubbles, from a bubbler consisting of a small, weighted tin can, the open end of which was covered with 8 or 10 thicknesses of butter cloth The air, cooled to 10° C., and thus practically fully saturated with moisture at that temperature, was piped through a jacketed copper pipe to the box in which the condenser was mounted, entering at the bottom through a glass tube in a perforated rubber stopper tightly fitted in a hole in the side of the box

The ventilating current, rising through the box, issued through a similar glass tube at the top of the opposite side. A ventilation of about 8 to 9 liters per minute was maintained through the box. A centigrade thermometer inserted through a perforated rubber stopper in the top of the box indicated the interior temperature.

Since the amount of moisture which fully saturates air at 10° C. will leave it only 42.1 per cent saturated at 24° C., it is obvious that, to secure the standard atmospheric conditions determined upon, all that is necessary is to see that the temperature of the box is maintained at 24° C., or as close to that figure as is practicable.

In order to provide means of heating the air when necessary, a coil of copper pipe in a hot-water bath was provided in the vicinity of the box, through which air could be by-passed, before reaching the box, by means of two stopcocks, as shown in the figure. In this manner, whenever, owing to external conditions, the temperature of the box tended to fall below 24° C., the incoming air could be led first through the copper coil in the hot-water bath and thus heated to the necessary extent. Since, when heated, no moisture would be lost, nor could it gain any, upon cooling to the temperature of the box, the relative humidity would comply with the conditions.

With the apparatus just described a large number of observations were made at a constant current and at frequencies varying from 135,000,000 to 8,330,000 cycles per second. The constant current employed caused a deflection of 30 divisions on the scale of the microammeter, corresponding to a current of 338 milliamperes flowing in the auxiliary tuned circuit.

This value of current was chosen because preliminary observations had shown that, at lethal frequencies, this current value always caused death in 10 minutes or less. In the great majority of instances ten mice weighing between 19 and 22 grams were used successively at each frequency and sometimes more were used.

The difference in frequency employed was in the neighborhood of 10 per cent. This accounts for the fact that many of the frequencies and wave lengths given in Table 1 are not integers. In that table are set forth the frequencies at which observations were made, the number of observations, the average time elapsing before death, the maximum time, the minimum time, and the usual time.

TABLE 1

Frequency times 10^6	Wave length	Number of observations	Average length of survival	Minimum length of survival	Maximum length of survival	Usual length of survival
	Meters		*Minutes*	*Minutes*	*Minutes*	*Minutes*
135	2.22	8	26.4	16.5	[1]	21-25
121.5	2.47	10	20.1	13.5	26.5	20-22.5

8.5	35.3	11	17.2	11.0	[3] 30.0	16-18
8.33	36.0	11	17.7	11.5	32.0	16-19

[1] 1 mouse survived 43 minutes unaffected.
[2] 3 mice survived 35 minutes unaffected.
[3] 1 mouse survived 30 minutes unaffected.

The average time of survival plotted against frequency is graphically shown in the chart which accompanies the table.

It will be seen from the graph that, starting at a frequency of 135,000,000 cycles per second, with a constant current maintained in the auxiliary circuit of 338 milliamperes, the lethality increases until at 66,000,000 cycles the mean time of survival has been reduced from an average of 26.8 minutes to one of 7.7 minutes, a reduction of 71.3 per cent. From this point, with a fluctuation of a minute or so in the mean time of survival, the lethality of the various frequencies

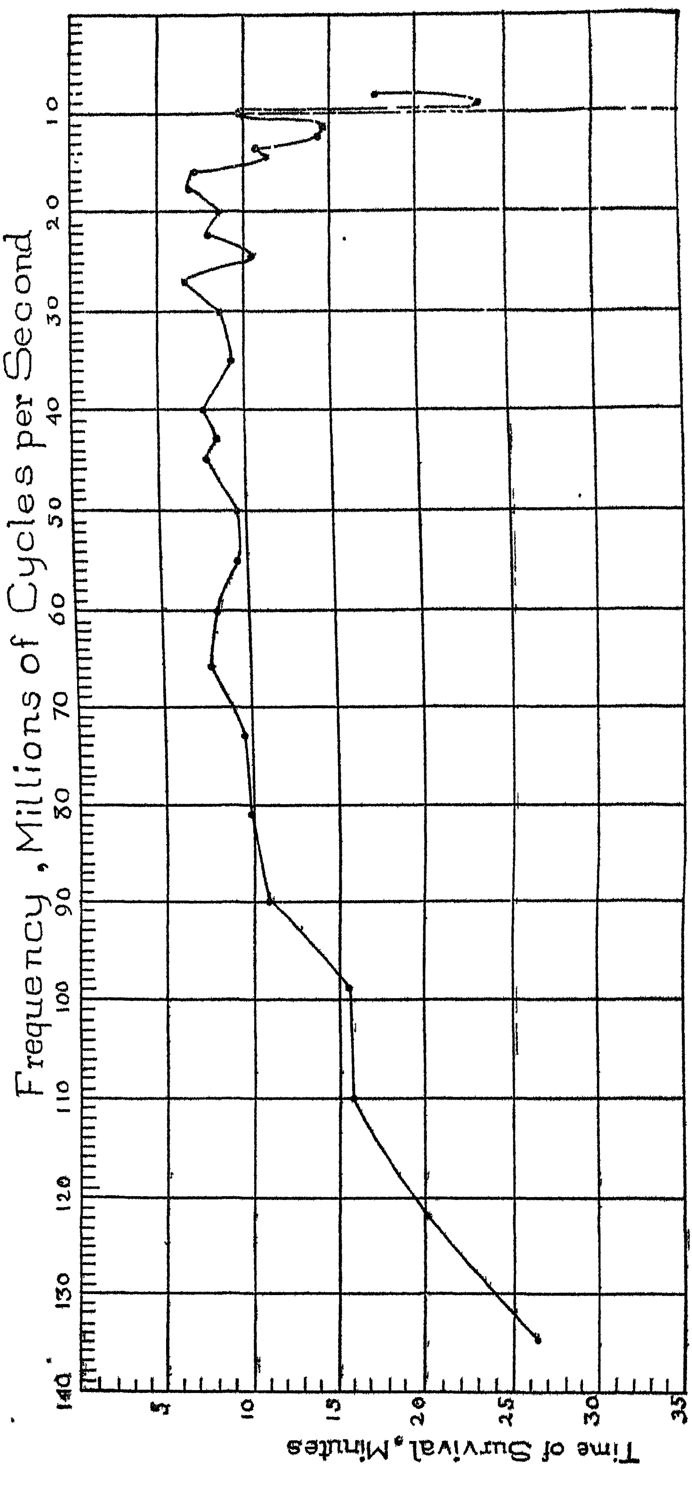

Chart showing the average time of survival of mice subjected to currents of various frequencies

observed maintains itself at more or less the same value over a frequency band of considerable width, i. e. from 66,000,000 to 27,000,000 cycles, at which point the low average period of survival of 6.65 minutes is recorded, or about 75 per cent less than the average time of survival at 135,000,000 cycles. At 21 3 million cycles the current becomes less lethal by about 40 per cent but at 18,000,000 cycles the current has about the same degree of lethality as at 27,000,000 cycles.

From 18,000,000 cycles the lethality on the whole diminishes, till at 11.1 million cycles the average time of survival increases to 14.5 minutes, 105 per cent longer than at 18,000,000 cycles. At a frequency of 10,000,000 cycles a recrudescence in lethality is observed, the mean time of survival falling to 9 65 minutes. At a frequency of 9,000,000 cycles, however, the lethality is comparatively low, the average time of survival being 23.5 minutes, nearly the same as it was at 135,000,000 cycles. At this frequency three mice survived exposures lasting 30 to 35 minutes apparently unharmed except for slight elevations of the body temperature. At 8 33 million cycles, beyond which point the observations were not carried, the lethality of the exposure seems on the increase, as well as at 8.5 million cycles, as the average time of survival of 11 mice was 17.2 and 17.7 minutes, respectively.

Discussion

From the configuration of the curve it is evident that the results just described are unexpected. Starting with a low lethal effect at the highest frequencies studied, a gradual increase in lethality is observed, followed by maintenance of fatality of the same order with successive small maxima and minima until at 18,000,000 cycles a peak is reached, followed by an abrupt decline, separated from the low point at 9,000,000 cycles by another maximum.

This result differs from what is usually observed in physical phenomena of this character. On the whole one would expect to find either that the lethality of a constant current was independent of frequency, or if dependent would show some simple relation thereto, e. g., be either inversely or directly proportional. That the lethality should be at first inversely and subsequently directly proportional to frequency is puzzling, and certainly not susceptible of any simple explanation.

At first one is tempted to assume that the results of the observation are apparent only. For instance, it might be urged that the apparent low lethality of the higher frequencies might be due to the "skin" effect of these frequencies upon the thermocouple.

As is well known, the high frequency resistance of conductors increases with the frequency, because, as this becomes greater, the current is confined to a surface pellicle of ever-diminishing thickness.

This so-called "skin effect" would occasion an increase with frequency in the apparent resistance of the thermocouple. Hence there would be a greater heating effect at the very high frequencies, and, as a result, a higher e. m. f. between the hot and cold junctions of the thermocouple, which would be reflected by a higher reading on the microammeter scale than would be justified by the actual oscillatory current flowing in the circuit.

That there may be some such effect at the highest frequencies is not denied, but how explain on these grounds the pronounced recession in lethality at the lower frequencies, where the "skin effect" is admittedly much less. Thus, we note that the lethality at 18.1 million cycles is about the same as at 24.3 million cycles, but very much greater (nearly 240 per cent) than at 9,000,000 cycles. Yet the skin effect, if important, should be more noticeable at 18,000,000 than at 9,000,000 cycles.

In view of the circumstance that, generally speaking, exposure to the oscillating current has very much less heating effect on dead than on living tissues, it may be suggested that, here, we are dealing with some action other than the direct heating effect observed at ordinary frequencies with diathermic apparatus.

In this case the heating effect is proportional to the product of the resistance and the square of the current Under the conditions of this study it is possible that the heat generated is caused by dielectric loss or hysteresis.

Again there is the possibility that the action is indirect rather than direct, the high-frequency current increasing the basal rate of metabolism, or perhaps causing heat retention through its influence upon thermogenic centers.

That the effects of exposure to the high-frequency current is capable of directly damaging tissue is shown by the sequelae already described, which are observed in mice subjected to a sublethal exposure.

As for the differential action of the different frequencies, which is the most striking of the effects observed, nothing except of a speculative nature can be advanced by way of explanation. For instance, it might be thought possible that at certain frequencies harmonics generated by the oscillator are in resonance with the natural period of organic molecules, particularly of animal proteids. These are well known to possess a very high molecular weight except for certain colloidal aggregates, perhaps the highest known molecular weights. Consequently, the natural period of resonance would be correspondingly low.

Nevertheless, in spite of the great size of the body molecules, the natural period of these, though relatively low compared with the molecules of simpler structure, would be sufficiently high to correspond to a wave length of from 0.5 to 3 or 4 millimeters, and hence to a fre-

quency of six times 10^{10} to seven times 10^9. The generation of definite harmonics of such a high order on the part of the oscillator seems altogether unlikely.

I am, however, indebted to Prof. George W. Pierce for the suggestion that the differential effects due to frequency may be caused by a mode of electromechanical vibration of the tissue cells, and for the accompanying reference to literature on the subject. Mechanical oscillations in solid elastic spheres have been given thorough mathematical treatment by Lamb.[4] A number of modes of vibration are analyzed and certain constants corresponding therewith are given. Some of the values of these constants (here designated "K") as given by Lamb, are $K=0.66$, 1 89, 2.93, 3.94, 4.96, 5.97, etc., the lowest value corresponding to the mode of vibration having the longest period. Since a solid elastic sphere is capable of vibrating in a number of different successive modes, each of which has a frequency greater than that preceding it, such a sphere is capable of responding to impressed oscillations of different frequencies.

The frequency, F, at which the sphere vibrates in a particular mode is given in simplest form by the equation—

$$F=K\frac{V}{D} \tag{1}$$

where F = Frequency of the particular mode of vibration.

K = The corresponding constant given by Lamb.

V = Velocity of the propagation of sound in the material composing the sphere.

D = Diameter of the sphere.

From this equation it follows directly that the diameter of a sphere vibrating in a particular mode at frequency, F, is given by the equation—

$$D=K\frac{V}{F} \tag{2}$$

In this case let us assume that the velocity of the propagation of sound through tissue cells is approximately that of its propagation through water, i. e., 1.45×10^5 centimeters per second. For the value of K let us take 0.66, which corresponds to the mode of vibration having the longest period and thus to the diameter of the smallest sphere capable of vibrating in some mode at that particular frequency. For F let us assume a value $F=40\times10^6$, a frequency somewhere in the middle of the band of lethal frequencies observed. Substituting these values in equation (2) we obtain for D, diameter of the sphere, 0.0024 centimeters or 24 microns. This diameter, while great for body cells, is, nevertheless, encountered in a number

---

[4] Lamb, H.: On the Vibrations of an Elastic Sphere. Proceedings of the London Mathematical Society Series, I, 1882, vol. 13, p. 189.

of cells in the nervous system. The diameter of the smallest sphere capable of oscillating at the highest frequencies worked with would be in the neighborhood of 7 microns, while at the lowest lethal frequency (lowest frequency of high lethality 10×10^6), this diameter would be 96 microns. This is greater than the diameter of any body cells except, perhaps, some of the giant pyramidal cells of the nervous system. However, in this instance one might venture the speculation that second or third order harmonics of the oscillator might, at the lower frequencies, possess sufficient energy to induce some form of electromechanical resonance in the body cells, although the fundamental frequency is too low to resonate with any except the sufficiently large body cells just mentioned.

As to the way in which electrical oscillations could induce mechanical vibrations in body cells, speculations are again in order. One possibility, at least, is that cell membranes act as dielectrics at the boundaries of cells. This would cause the contiguous surfaces of cells to act as condensers resulting in stresses of alternating polarity at the impressed frequency. A reinforcement of the effect resulting in mechanical vibrations would reasonably be expected when the frequency of the applied stresses approaches the natural period for mechanical vibrations of the cell. It would not, however, be expected that this frequency is critical, as such a system must, of necessity, be highly damped. So, if responsive, the response would merely be greater for a range of frequencies in the neighborhood of the frequency of mechanical vibrations.

Conclusions

On the basis of the data gathered in the foregoing experiments, the following conclusions are permitted:

1. When small laboratory animals are placed in a box of insulating material and subjected to the action of a high frequency oscillating current in the field of a condenser resonating a tuned circuit, severe symptoms are caused which may result in death if the exposure is prolonged. Part at least, of the symptoms is due to heat retention.

2. This effect is most marked in a certain band of frequencies extending from $F=66 \times 10^6$ cycles to $F=18.3 \times 10^6$ cycles, the effect diminishing in one direction from a band extending from $F=66 \times 10^6$ to $F=135 \times 10^6$ and in the other from $F=18.3 \times 10^6$ to $F=9 \times 10^6$.

3. There is, consequently, at constant current, under the conditions of the experiments, a differential action with respect to frequency, the lethality of a constant current being in one region of the spectrum inversely and in another portion directly proportional to frequency.

4. In the band of frequencies studied, successive maxima and minima with respect to lethality occur which are most pronounced as the lower frequencies are approached.

Finally it may be remarked that here we are dealing with a band in the spectrum of radiant energy which as yet has been little studied in its effects on living cells. Since frequency is the sole differentiating characteristic in the whole band of radiant energy it is perhaps to be expected to find that in electromagnetic waves, frequency is a determining factor in their mode of action upon living organisms. It is thought that this is a field which will well repay further study.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Report on the First Results of Laboratory Work on Malaria in England. S P. James Publication by the Health Section of the League of Nations, Geneva, 1926. (Abstract by L D. Fricks.)

While this is a report of observations made on artificially infected mosquitoes in the laboratory, it contains valuable suggestions to those who are engaged in malaria control. These observations were made in connection with the malarial treatment of general paralysis. Two thousand six hundred and thirty-eight *Anopheles maculipennis* were employed, 532 of which became infected and were used to bite 145 persons, 109 of whom developed malaria. Colonel James observes that it is no easy matter to infect mosquitoes with malaria even under the most favorable laboratory conditions. The conditions most favorable to the development of the *Plasmodia* in the mosquito causes high mortality among the mosquitoes themselves. To produce infective mosquitoes it is necessary that they be kept, after feeding on a malaria carrier, at a temperature of 24° C. in an atmosphere saturated with moisture, and the mosquitoes must be given frequent feedings—daily or every other day. It would seem that the required conditions for producing naturally infected mosquitoes are only rarely met. In addition, very few malaria patients are good infectors of *Anopheles* The extreme delicacy of these requirements indicate to the author that malaria should be dealt with in the houses of the people rather than in the environment, and that a waste of effort is involved in measures directed toward general mosquito destruction.

(Abstractor's note: LePrince pointed out the importance of destroying engorged *Anopheles* in houses as a malaria-control measure in the Panama Canal Zone many years ago)

Problems in Malaria Control. W E. Deeks. Fourteenth Annual Report United Fruit Company, 1925, pp. 170–186. (Abstract by L. D. Fricks.)

Doctor Deeks states that malaria is responsible for 40 per cent of the sickness on the plantations of the United Fruit Company, and it is therefore the most important single factor in lowering the efficiency of labor. A description is given of certain United Fruit Company plantations and the extent of the malaria problem thereon indicated. Among the conditions which influence the incidence of

malaria on these plantations are listed the following: Rainfall; location of camps; screening of quarters; and impaired physical condition frequently due to complicating diseases. Measures of malaria control recommended are: Mosquito control for a radius of two miles around the settlements, careful selection of new camp sites; stabilizing of population, and screening of houses and cure of carriers.

AMERICAN PUBLIC HEALTH ASSOCIATION TO MEET IN BUFFALO, OCTOBER 11-14, 1926

What is new in public health? How are communities, urban and rural, coping with the public health problems that confront administrators, public health officers, nurses, and inspectors? These questions will be answered, and problems that have been the subject of laboratory research will be discussed by specialists at the fifty-fifth annual meeting of the American Public Health Association to be held in Buffalo, N. Y., October 11-14, 1926. This association is the professional society of the public health workers of North America.

It is expected that this year's meeting will be the largest and the most interesting of all the annual gatherings of the association, and this expectation is fully justified on the basis of the announcements contained in the preliminary program recently issued. The sessions are arranged in four sections—general sessions; special sessions, which have been developed around subjects of timely and lively interest; sessions of the nine scientific sections of the association; and the special program arranged by the New York State Conference of Health Officers and Public Health Nurses, which the State health commissioner, Dr. Matthias Nicoll, has called to meet in conjunction with the American Public Health Association.

The meeting will begin on Monday morning, October 11, and will end with a special dinner session on Thursday evening, October 14. The headquarters of the association will be in the Hotel Statler, where all sessions will be held. The preliminary program and other information regarding the meeting may be had by addressing Homer N. Calver, Executive Secretary, American Public Health Association, 370 Seventh Avenue, New York City.

AMERICAN DIETETIC ASSOCIATION MEETING AT ATLANTIC CITY

The American Dietetic Association will hold its ninth annual meeting at Atlantic City, October 11, 12, and 13, 1926. The program will include papers and discussions on both scientific and administrative matters.

Dr. J. J. R. McLeod, of the University of Toronto, will address the convention on the advances made in physiology, and Dr. Julius Stieglitz, of the University of Chicago, will speak on the recent advances made in chemistry.

Arrangements have been made for some interesting exhibits, both commercial and noncommercial

Dr Ruth Wheeler, professor of physiology at Vassar, is the president of the association.

DEATHS DURING WEEK ENDED AUGUST 28, 1926

Summary of information received by telegraph from industrial insurance companies for week ended August 28, 1926, and corresponding week of 1925 (From the Weekly Health Index, September 1, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Aug 28, 1926	Corresponding week, 1925
Policies in force	64, 869, 549	60, 879, 605
Number of death claims	10, 175	10, 590
Death claims per 1,000 policies in force, annual rate	8 2	9. 1

Deaths from all causes in certain large cities of the United States during the week ended August 28, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, September 1, 1926, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population.

[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.

[3] Data for 63 cities.

[4] Deaths for week ended Friday, Aug. 27, 1926.

[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population. Atlanta 31, Baltimore 15, Birmingham 39, Dallas 15, Fort Worth 14, Houston 25, Indianapolis 11, Kansas City, Kans., 14, Louisville 17, Memphis 38, New Orleans 26, Norfolk 38, Richmond 32, and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

SUMMARY OF MONTHLY REPORTS FROM STATES

The following summary of monthly State reports is published weekly and covers only those States from which reports are received during the current week.

State	Cerebrospinal meningitis	Diphtheria	Influenza	Malaria	Measles	Pellagra	Poliomyelitis	Scarlet fever	Smallpox	Typhoid fever
July, 1926										
Florida	3	66	301	33	55	7	8	14	48	84

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended August 21, 1926, 37 States reported 655 cases of diphtheria. For the week ended August 22, 1925, the same States reported 879 cases of this disease. Ninety-eight cities, situated in all parts of the country and having an aggregate population of more than 30,200,000, reported 397 cases of diphtheria for the week ended August 21, 1926. Last year for the corresponding week they reported 388 cases. The estimated expectancy for these cities was 541 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles.—Thirty-five States reported 975 cases of measles for the week ended August 21, 1926, and 401 cases of this disease for the week ended August 22, 1925. Ninety-eight cities reported 238 cases of measles for the week this year, and 170 cases last year.

Poliomyelitis.—The health officers of 37 States reported 99 cases of poliomyelitis for the week ended August 21, 1926. The same States reported 296 cases for the week ended August 22, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-seven States—this year, 858 cases, last year, 705 cases; 98 cities—this year, 281 cases; last year, 285 cases; estimated expectancy, 238 cases.

Smallpox.—For the week ended August 21, 1926, 37 States reported 129 cases of smallpox. Last year for the corresponding week they reported 135 cases. Ninety-eight cities reported smallpox for the week as follows: 1926, 12 cases; 1925, 29 cases; estimated expectancy, 23 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—One thousand two hundred and fifty-one cases of typhoid fever were reported for the week ended August 21, 1926, by 36 States. For the corresponding week of 1925, the same States reported 1,319 cases of this disease. Ninety-eight cities reported 237 cases of typhoid fever for the week this year and 314 cases for the corresponding week last year. The estimated expectancy for these cities was 235 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 94 cities, with a population of nearly 29,700,000, as follows: 1926, 324 deaths; 1925, 309 deaths.

City reports for week ended August 21, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported

The following table gives the rates per 100,000 population for 102 cities for the five-week period ended August 21, 1926, compared with those for a like period ended August 22, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925, and 1926, respectively, authoritative figures for many of the cities not being available. The 102 cities reporting cases had an

estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926 The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, July 18 to August 21, 1926—Annual rates per 100,000 population—Compared with rates for the corresponding period of 1925 [1]

Amoy	2	----	0	0	0	0
Shanghai	----	----	----	----	----	----

[1] One plague-infected rat was found in the port during the week.

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Iraq.—Basra.

British India.—Chittagong, Cochin, Tuticorin.

Ceylon.—Colombo

Federated Malay States.—Port Swettenham.

Straits Settlements.—Penang, Singapore.

Dutch East Indies.—Batavia, Surabaya, Samarang, Belawan-Deli, Palembang, Sabang, Makassar, Menado, Banjermasin, Balik-Papan, Tarakan, Padang, Samarinda.

Sarawak.—Kuching.

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao.

Portuguese Timor.—Dilly.

Philippine Islands.—Manila, Iloilo, Jolo, Cebu, Zamboanga.

French Indo-China.—Turane, Haiphong.

China.—Hongkong.

Formosa.—Keelung.

Kwantung—Port Arthur, Dairen.
Japan—Yokohama, Osaka, Nagasaki, Moji, Kobe, Niigata, Tsuruga, Hakodate, Simonoseki
Korea.—Chemulpo, Fusan.
Manchuria.—Antung, Mukden, Changchun, Harbin.
U S S. R—Vladivostok

AUSTRALASIA AND OCEANIA

Australia—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island
New Guinea—Port Moresby
New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.
New Caledonia—Noumea.
Fiji—Suva
Hawaii—Honolulu

AFRICA

Egypt—Port Said, Suez
Anglo-Egyptian Sudan—Port Sudan, Suakin.
Eritrea—Massaua
French Somaliland—Jibuti
British Somaliland—Berbera
Italian Somaliland—Mogadiscio.
Kenya.—Mombasa
Zanzibar—Zanzibar.
Tanganyika—Dar-es-Salaam.
Seychelles.—Victoria
Mauritius—Port Louis
Madagascar—Tamatave, Majunga.
Portuguese East Africa—Mozambique, Beira, Lourenço-Marques
Union of South Africa—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

British India.—Calcutta
Dutch East Indies.—Pontianak.
China.—Shanghai.

ALGERIA

Plague—Bona—August 14, 1926.—A case of plague was reported, August 14, 1926, at Bona, Algeria.

CANADA

Communicable diseases—Week ended August 21, 1926.—The Canadian Ministry of Health reports cases of certain communicable diseases in six Provinces of Canada for the week ended August 21, 1926, as follows:

Disease	Nova Scotia	New Brunswick	Quebec	Ontario	Manitoba	Saskatchewan	Total
Cerebrospinal fever			1	1		1	3
Influenza	10						10
Poliomyelitis		2		2			4
Smallpox				7	2	1	10
Typhoid fever	2	4	7	9	6		28

Vital statistics—Quebec—June, 1926.—Births and deaths in the Province of Quebec for the month of June, 1926, have been reported as follows:

Estimated population	2,570,000
Births	6,653
Birth rate per 1,000 population	31 06
Deaths (all causes)	2,884
Death rate per 1,000 population	13 46
Deaths under 1 year	837
Infant mortality rate	125 80
Deaths from—	
Cancer	123
Cerebrospinal meningitis	10
Diabetes	20
Diphtheria	32
Deaths from—Continued.	
Heart diseases	404
Influenza	95
Measles	30
Poliomyelitis (infantile paralysis)	1
Scarlet fever	14
Syphilis	18
Tuberculosis (pulmonary)	235
Tuberculosis (other forms)	69
Typhoid fever	22
Whooping cough	41

CANARY ISLANDS

Plague—Teneriffe—August 2, 1926.—Information received under date of August 5, 1926, shows two cases of plague reported present August 2, 1926, at Teneriffe, Canary Islands, occurring in the Cristianos district.

CHINA

Cholera—Swatow.—During the week ended July 31, 1926, 14 cases of cholera were reported at Swatow, China. It was stated that the mortality from the disease was low.

ECUADOR

Plague—Guayaquil—July 16–31, 1926.—During the period July 16 to 31, 1926, five cases of plague with two deaths were reported at Guayaquil, Ecuador.

Plague-infected rats.—During the same period, of 10,148 rats taken 14 were found plague infected.

EGYPT

Plague—July 23–29, 1926.—Plague has been reported in Egypt as follows: In cities—Alexandria, July 27, two cases; Suez, July 29, two cases, bubonic; in Provinces—Behera, July 23–29, two cases, bubonic; Charkieh, July 27, one case fatal, septicemic; Minieh, July 24, one case, fatal, bubonic.

Plague in Egypt—January 1–July 29, 1926

Place	Cases	Deaths	Date of first case 1926	Date of last case 1926
City:				
Alexandria	5	1	Mar. 10	July 27
Suez	18	11	Mar. 27	July 29
Province:				
Behera	20	7	June 3	July 29
Beni-Suef	45	*24	May 10	July 15
Charkieh	1	1	June 27	July 27
Dakahlia	1	1	Apr. 22	May 22
Fayoum	1	1	May 4	May 4
Gharbieh	12	6	Mar. 9	June 2
Girgeh	6	4	June 26	July 3
Minieh	3	2	Mar. 4	July 24

FINLAND

Communicable diseases—June, 1926.—During the month of June, 1926, communicable diseases were reported in the Republic of Finland as follows:

Disease	Cases	Disease	Cases
Diphtheria	42	Poliomyelitis	3
Dysentery	6	Scarlet fever	96
Lethargic encephalitis	2	Typhoid fever	40
Paratyphoid fever	135		

FRANCE

Plague—Saint Ouen—August 14, 1926.—Two cases of plague were reported at St Ouen, a suburb of Paris, France, August 14, 1926.

GERMANY

Mortality—Karlsruhe, Baden—Year 1925 (comparative)—Information received under date of July 30, 1926, relative to vital statistics of the city of Karlsruhe, Baden, shows for the year 1925 the occurrence of 1,748 deaths from all causes in a population of 144,700; previous year, 1,738. For the years 1918, 1921, and 1923 the number of deaths were 2,320, 1,907, and 1,962, respectively. The decrease for the years 1924 and 1925 was stated to have been mainly due to decreased infant mortality, and this improvement was attributed to improved living conditions and better education in the care and treatment of infants

Causes of death—During the year 1925 tuberculosis caused 206 deaths, of which 167 were of tuberculosis of the lungs and larynx.

Cancer.—Increased mortality from cancer has been noted. In 1924 there were reported 206 deaths from cancer; in 1925 the number fell to 199; from 1920 to 1923 the number varied from 154 to 146.

GUATEMALA

Gastroenteritis—Guatemala—July, 1926.—During the month of July, 27 deaths from gastroenteritis were reported at Guatemala. Population, 220,000.

JAPAN

Further relative to plague at Yokohama.—Under date of August 7, 1926, two additional cases of plague [1] were reported at Yokohama, Japan, occurring within the city limits but not at the same distance from the original focus. One case occurred in a coolie employed in the canal section and one in an employee of a silk warehouse, a large reinforced building outside the customs compound.

[1] Public Health Reports, Aug. 27, 1926, p. 1867.

MEXICO

Gastroenteritis — Chihuahua — Mazatlan — August 16–22, 1926.—During the week ended August 22, 1926, 7 deaths from gastroenteritis were reported at Chihuahua and 7 at Mazatlan, Mexico. Population, 48,000 and 25,000, respectively.

VENEZUELA

Gastroenteritis—Caracas—July, 1926.—During the month of July, 1926, 58 deaths from gastroenteritis were reported at Caracas, Venezuela. Of these, 42 deaths were in children under two years of age; 16 were in persons over two years.

VIRGIN ISLANDS

Communicable diseases—July, 1926.—Communicable diseases were reported in the Virgin Islands of the United States during the month of July, 1926, as follows:

Island and disease	Cases	Remarks
St Thomas and St John		
Chancroid	1	St. Croix.
Gonorrhea	4	St John, 1.

TREASURY DEPARTMENT

PUBLIC HEALTH REPORTS

ISSUED WEEKLY

BY THE UNITED STATES PUBLIC HEALTH SERVICE

VOLUME 41 :: :: NUMBER 38

SEPTEMBER 17 - 1926

SPECIAL ARTICLE

Notifiable Diseases Reported in Large Cities, 1926

WASHINGTON
GOVERNMENT PRINTING OFFICE
1926

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D C

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM
THE SUPERINTENDENT OF DOCUMENTS

PUBLIC HEALTH REPORTS

VOL. 41 | SEPTEMBER 17, 1926 | No. 38

THE NOTIFIABLE DISEASES

PREVALENCE DURING 1925 IN CITIES OF OVER 100,000

The following tables were compiled from data furnished by the health officers of the cities They include all cities of 100,000 population or over in the United States

The following is a list of the diseases included·

Anthrax.	Pneumonia (all forms)
Cerebrospinal fever	Poliomyelitis
Chicken pox	Rabies in animals.
Dengue	Rabies in man
Diphtheria.	Scarlet fever
Influenza.	Septic sore throat.
Lethargic encephalitis.	Smallpox.
Malaria	Tuberculosis (all forms and pulmonary).
Measles	Typhoid fever
Mumps	Typhus fever
Pellagra.	Whooping cough.

The populations given, and which were used in computing the rates, were estimated as of July 1, 1925 Estimates of population by the Bureau of the Census are based upon the assumption that the annual increase in the population of any city since 1920 is equal to the annual increase between 1910 and 1920 as shown by the returns of the two Federal censuses. This method gives an estimate which is approximately correct for most of the cities. In a few cases, however, where there is reason to believe that the results thus obtained are far from correct, no estimate is made. The number of cases and deaths occurring from each disease in these cities is given but no rates are computed.

The estimated expectancy given in the tables for some of the diseases is the result of an attempt to ascertain from the experience of recent years how many cases of the disease under consideration might be expected in 1925 In most instances the estimated expectancy is the median number of cases reported by the city for the years 1918 to 1924, inclusive. When several epidemics have occurred

during these years, or when for other reasons the median is not satisfactory, epidemic years are excluded, and the estimated expectancy is the mean of the number of cases reported for the nonepidemic years The aim has been to ascertain how many cases of each disease may reasonably be expected in the absence of epidemics.

The column headed "Number of years" shows the number of years for which data were available for each city.

In comparing the figures for 1925 with the estimated expectancy, averages, or with reports for preceding years, it should be borne in mind that for several years there has been a gradual improvement in the reporting of communicable diseases An increase in the number of cases reported may be due to better reporting rather than to an increase in the number of cases occurring

In studying these tables it should be kept in mind that a relatively large number of reported cases of a communicable disease as indicated by a high case rate (and more especially when accompanied by a relatively small number of deaths, as indicated by a low fatality rate) usually means that the health department of that city is active and that the cases of the disease are being well reported by the practicing physicians. It does not usually mean that the disease is more prevalent in that city than in other cities A high fatality rate may mean that the disease was unusually virulent in a city; that the physicians did not treat the disease in that city with the success usual elsewhere; or that the practicing physicians did not report all of their cases to the health department. On the other hand, an unusually low fatality rate may be due to the fact that the disease in the city was unusually mild; that the physicians treated it with unusual success; that the practicing physicians reported their cases satisfactorily; or that the registration of deaths was incomplete or the assignment of the causes of death inaccurate.

Cities which did not report either cases or deaths of a certain disease in 1925 (except smallpox) are not included in the table for that disease

The following table gives a comparison of the rates for some of the principal communicable diseases in the large cities of the United States for the years 1922, 1923, 1924, and 1925:

	Cases		Deaths	
	Number of cities	Cases per 1,000 population	Number of cities	Deaths per 1,000 population
Chicken pox:				
1922	68	1.60	68	0.001
1923	77	2.02	77	.001
1924	82	2.45	82	.001
1925	69	1.89	69	.001
Diphtheria:				
1922	73	2.25	73	.16
1923	77	1.97	77	.13
1924	82	1.67	83	.11
1925	69	1.39	69	.10

	Cases		Deaths	
	Number of cities	Cases per 1 000 population	Number of cities	Deaths per 1,000 population
Influenza				
1922			70	0 16
1923			77	21

COURT DECISIONS RELATING TO PUBLIC HEALTH

Order of State board of purification of waters sustained.—(Rhode Island Supreme Court; Board of Purification of Waters *v.* Town of East Providence, 133 A 812; decided June 25, 1926.) The Rhode Island Board of Purification of Waters, after due notice and hearing, made an order directing the town of East Providence "to adopt, use, and operate some practicable and reasonably available system or means to prevent" sewage pollution of the Seekonk River. It was undisputed that the sewage deposited by the town constituted a

pollution and that other municipalities also polluted the river by the discharge of sewage into it. The constitutionality of chapter 125 of the General Laws of 1923, under which the board acted, was attacked by the town, and also the order of the board was alleged to be unreasonable. The supreme court, however, decided that the law in question was constitutional and sustained the board's order.

Garbage ordinance held not violated—(Kansas Supreme Court; City of Wichita *v.* Killion, and Same *v.* Landrum, 245 P. 1056; decided May 8, 1926.) A restaurant owner in the city of Wichita deposited scraps of meat and bones and refuse from the table in his restaurant in a receptacle kept for that purpose and this material would then from time to time be carried in a paper sack or bag to a place just outside the city limits, where it would be fed to some dogs, rabbits and other pets owned by the restaurant keeper. The material so fed to the animals never reached the garbage can used to contain the garbage from the restaurant. An ordinance of Wichita provided for the collection of garbage exclusively by a licensed contractor and prohibited other persons from collecting or removing garbage. The ordinance contained the following:

> That the term "garbage" as used here shall be defined and construed to mean "all organic waste or residue of animal food or vegetable matter from kitchens and dining rooms, and for the preparation or dealing in storage of meats, fowls, fruits, vegetables, and cream."

In prosecutions for violating the ordinance the supreme court held that the defendants were not guilty because the material withheld and fed to the animals was not garbage within the meaning of the ordinance.

Order of State board of health prohibiting boating on pond which was source of city water supply upheld—(Vermont Supreme Court; State *v.* Quattropani, 133 A. 352; decided May 5, 1926.) The defendant was convicted of violating an order of the State board of health prohibiting boating on a certain pond which was the source of the water supply of the city of Montpelier. This order, which was adopted by the board under statutory authority to make regulations to prevent the pollution of waters used for public water supply, was upheld by the supreme court.

Refusal to pasteurize milk not ground for denial of permit.—(Missouri Supreme Court; State ex rel. Knese et al. *v.* Kinsey et al., Board of Public Service, 282 S. W. 437; decided April 9, 1926.) In mandamus proceedings to compel the issuance of permits to milk dealers the supreme court decided that the board of public service of the city of St. Louis, acting under a city ordinance, could not refuse to issue such permits where the reason for so doing was the refusal of the milk dealers to pasteurize their milk. The court stated that

the milk dealers "have a right to deal in it [raw milk] under the statutes and constitution, and a denial of that right is supported by neither law nor reason."

PUBLIC HEALTH ENGINEERING ABSTRACTS

How Pasteurizing Plants are Inspected. Anon Health News, New York State Department of Health, vol. 3, No. 26, June 28, 1926, pp 102–103 (Abstract by Isador W Mendelsohn)

In New York State there are approximately 963 milk pasteurizing plants, of which about 500 ship their supply to and are under the control of New York City The remainder supply 92 "upstate" municipalities and are under the supervision of the State department of health All pasteurizing plants in the latter group must meet the requirements of the Sanitary Code and comply with the regulations of the department regarding construction, sanitation, equipment, and operation The division of sanitation supervises milk pasteurization.

The investigation of a pasteurizing plant in cooperation with the local health authorities includes the following: (1) Careful inspection in and around the plant and examination of all apparatus before the pasteurizing process is commenced, to determine the cleanliness of the plants, (2) observance of heating temperature, holding period, method of handling milk, accuracy of recording thermometer, method of cleaning the apparatus, pipes, and pumps after pasteurization; (3) collection of milk samples, for determination of bacterial content from mixed raw milk, from the holder after a 30-minute period, the cooler, and the bottle filler, (4) preparation of reports and transmission of copies to the plant owner, local health officer, and the district State health officer

The number of milk pasteurizing plants in the State outside of the New York City plants has increased from 315 in 1922 to 463 in 1925

A Successful Experiment in Milk Control. B. K Wilbur The Listening Post, Pennsylvania State Department of Health, vol. 4, No. 38, May and June, 1926, pp. 23–28. (Abstract by A. L. Dopmeyer.)

Geographical lines separating towns in thickly settled suburban districts in Pennsylvania have been found to make the control of the town milk supply difficult where one town had strict regulations and careful inspection, as compared to opposite conditions in an adjoining town. In order to eliminate the resulting evils, and as a result of a milk-borne typhoid fever epidemic in a community suburban to Philadelphia, a plan for coordinating the milk control activities of a number of towns was adopted, which method, after four years' operation, is said to be a success.

The following requirements were agreed upon by the boards representing the cooperating communities; (1) Uniform regulations, milk rules; (2) one chief milk control officer with necessary assistants; (3) a central laboratory control; (4) a central office of control; (5) equitable division of expenses, (6) a representative committee of management.

The operation of this plan for four years in what is known as Milk Control District No 1, State of Pennsylvania, has resulted in reduction of cost of milk control in each unit; the avoiding of overlapping of inspection and duplicate analyses, the reduction of the varieties of milk sold to three standard brands, the reduction of the average bacteria count of all milk sold, progressively from year to year to 39,400; improvement in the sanitary grades of the milk dealers; the creation of a tuberculosis free area; and the reduction of infant mortality from faulty nutrition and intestinal disorders

Relation Between the Bacterial Count of Whole Milk and That of the Cream and Skim Milk Separated from it. C. S Leete (Jour. Agr. Research (U. S), 31 (1925), No 7, pp 695-699) From Experiment Station Record, United States Department of Agriculture, vol. 54, No 6, April, 1926, p 572

"The results are reported of investigations in the Bureau of Dairying, United States Department of Agriculture, on the bacterial count as determined by the plate method of whole milk and the cream and skim milk separated from it by a centrifugal separator and by gravity. One hundred samples of whole milk having bacterial counts ranging from 9,000 to 14,410,000 and averaging 435,240 per cubic centimeter were separated by the centrifugal method The bacterial counts of the cream from this milk ranged from 7,000 to 18,600,000 and averaged 500,830 per cubic centimeter. The bacterial counts of the skim milk ranged from 9,000 to 7,500,000 and averaged 312,740. In 70 of the samples which showed increases in the count of the cream, as compared with the whole milk, the average increase was 23.87 per cent, and in 23 samples showing decreases the average decrease was 14 06 per cent Seven of the samples showed no change. Twenty-five samples of whole milk ranging in bacterial count from 2,000 to 850,000 and averaging 135,880 per cubic centimeter were separated by the gravity method. The bacterial counts of the cream from such milk ranged from 5,000 to 1,700,000, averaging 283,680. The bacterial counts of the skim milk ranged from 900 to 180,000 and averaged 33,556.

"The author concludes that gravity-separated cream shows a much higher increase in bacterial count than cream separated by the centrifugal method, but that there appears to be no reason for the custom of allowing much higher bacterial counts for cream than for milk in many milk ordinances."

The Destruction of Mosquito Larvæ in Artificial Breeding Places by the Evacuation of the Water. A. Catanei. Arch. de L'Inst Past. d'Algerie, vol 3, No. 2, 1925, pp. 142–145. (Abstract by M. A. Barber)

The evacuation of the water from artificial breeding places is not a sufficient antilarval measure, because pupæ and the larger larvæ of mosquitoes may survive in the moist bottom of the reservoir long enough to reach maturity. If such temporary evacuation of water is the only measure employed it is advisable to wash out the basin with running water after it is evacuated.

DEATH RATES IN A GROUP OF INSURED PERSONS

Rates for Principal Causes of Death for July, 1926

The accompanying table is taken from the Statistical Bulletin for August, 1926, published by the Metropolitan Life Insurance Co., and presents the mortality experience of the industrial insurance department of the company for July, 1926, as compared with June, 1926, and with July and year, 1925 The rates are based on a strength of approximately 17,000,000 insured persons in the industrial populations of the United States and Canada

The Bulletin states.

> The health situation in the industrial populations of the United States and Canada showed, in July, the usual seasonal improvement The death rate (8 2 per 1,000) marked a decided drop from the June figure (9 5) and was also slightly lower than for July of last year Every cause of death listed in the accompanying table, with the exception of typhoid fever, diarrheal diseases, and accidents, showed a reduction as compared with June, and even these three registered lower rates than in July of last year.

The most marked declines were shown for influenza, pneumonia, and measles, but appreciable decreases were also recorded in mortality from tuberculosis and the "degenerative diseases "

The Bulletin states that it will take more pronounced improvement than that shown in July to overcome in the final half of this year the relatively high mortality of the first half of the year. It is still possible, but not probable, it is stated, that the year 1926 will show an improvement in health conditions over 1925.

Death rates (annual basis) for principal causes per 100,000 lives exposed, June and July, 1926, and July and year 1925

[Industrial department, Metropolitan Life Insurance Co.]

Cause of death	Rate per 100,000 lives exposed[1]

Hawaii Territory	0	14	30		11		0	3	0	14
Rhode Island	1	14	0	1	101		0	13	0	0
August, 1926										
Arizona		18		1	5		1	14	1	10
Connecticut	1	31	12	1	121		5	53	0	35
District of Columbia	1	27	6		8	0	1	33	2	14
Georgia	0	42	67	322	12	16	1	20	14	321

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended August 28, 1926, 36 States reported 738 cases of diphtheria For the week ended August 29, 1925, the same States reported 855 cases of this disease. Ninety-eight cities, situated in all parts of the country and having an aggregate population of more than 30,300,000, reported 377 cases of diphtheria for the week ended August 28, 1926 Last year for the corresponding week they reported 409 cases The estimated expectancy for these cities was 540 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics

Measles —Thirty-two States reported 746 cases of measles for the week ended August 28, 1926, and 361 cases of this disease for the week ended August 29, 1925 Ninety-eight cities reported 156 cases of measles for the week this year, and 153 cases last year.

Poliomyelitis —The health officers of 37 States reported 118 cases of poliomyelitis for the week ended August 28, 1926. The same States reported 295 cases for the week ended August 29, 1925.

Scarlet fever —Scarlet fever was reported for the week as follows: Thirty-six States—this year, 662 cases; last year, 630 cases; 98 cities — this year, 318 cases; last year, 250 cases, estimated expectancy, 245 cases.

Smallpox.—For the week ended August 28, 1926, 36 States reported 103 cases of smallpox Last year for the corresponding week they reported 101 cases Ninety-eight cities reported smallpox for the week as follows: 1926, 23 cases; 1925, 44 cases; estimated expectancy, 26 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—One thousand two hundred and sixty-three cases of typhoid fever were reported for the week ended August 28, 1926,

by 35 States For the corresponding week of 1925, the same States reported 1,262 cases of this disease. Ninety-eight cities reported 233 cases of typhoid fever for the week this year and 257 cases for the corresponding week last year. The estimated expectancy for these cities was 243 cases.

Influenza and pneumonia—Deaths from influenza and pneumonia were reported for the week by 92 cities, with a population of more than 29,600,000, as follows: 1926, 289 deaths; 1925, 360 deaths.

City reports for week ended August 28, 1926

The "estimated expectancy" given for diptheria, poliomyelitis, scarlet fever, smallpox, and tyhpoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy

[1] Dengue—4 cases at Charleston, S C, and 1 case at Savannah, Ga

The following table gives the rates per 100,000 population for 102 cities for the five-week period ended August 28, 1926, compared with those for a like period ended August 29, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 102 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926 The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926 The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, July 25 to August 28, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925 [1]

FOREIGN AND INSULAR

THE FAR EAST

Report for two weeks ended August 21, 1926—The following reports for the two weeks ended August 21, 1926, were transmitted by the far eastern bureau of the secretariat of the health section of the League of Nations, located at Singapore, to the headquarters at Geneva:

Week Ended Saturday, August 14. 1926

Maritime towns	Plague		Cholera		Smallpox	
	Cases	Deaths	Cases	Deaths	Cases	Deaths
Egypt, Alexandria	0	0	0	0	1	1
British India						
Calcutta	--------	0	--------	5	2	1
Bombay	--------	2	--------	0	6	4
Madras	--------	0	------	0	5	3
Negapatam	--------	0	--------	5	0	0
Karachi	--------	0	--------	0	3	1
Siam, Bangkok	0	0	2	1	9	5
Dutch East Indies, Cheribon [1]	0	0	0	0	0	0
French Indo-China, Saigon and Cholon	0	0	0	0	2	0
China						
Amoy	2	--------	2	0	0	0
Shanghai	0	0	171	78	0	0
Kwantung, Dairen	0	0	0	0	1	0
Manchuria, Harbin	0	0	36	9	0	0

[1] One infected rat was found in the port during the week

Telegraphic reports from the following maritime towns indicated that no case of plague, cholera, or smallpox was reported during the week:

ASIA

Iraq—Basra

British India—Chittagong, Cochin, Tuticorin, Vizagapatam.

Ceylon—Colombo.

Federated Malay States—Port Swettenham.

Straits Settlements—Penang, Singapore

Dutch East Indies.—Batavia, Surabaya, Samarang, Belawan-Deli, Palembang, Sabang, Makassar, Banjermasin, Balik-Papan, Tarakan, Padang, Samarinda, Pontianak

Sarawak—Kuching

British North Borneo.—Sandakan, Jesselton, Kudat, Tawao.

Portuguese Timor.—Dilly.

Philippine Islands—Manila, Iloilo, Jolo, Cebu, Zamboanga.

French Indo-China—Turane, Haiphong.

China—Hongkong.

Formosa.—Keelung

Kwantung.—Port Arthur.

Japan.—Yokohama, Osaka, Nagasaki, Moji, Kobe, Niigata, Tsuruga, Hakodate, Simonoseki.

Korea.—Chemulpo, Fusan.

Manchuria.—Antung, Mukden, Changchun.

U. S. S. R.—Vladivostok.

AUSTRALASIA AND OCEANIA

Australia.—Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Port Darwin, Broome, Fremantle, Carnarvon, Thursday Island.

New Guinea.—Port Moresby.

New Zealand.—Auckland, Wellington, Christchurch, Invercargill, Dunedin.

New Caledonia.—Noumea.

Fiji.—Suva.

Hawaii.—Honolulu.

AFRICA

Egypt.—Port Said, Suez.

Anglo-Egyptian Sudan.—Port Sudan, Suakin.

Eritrea.—Massaua.

French Somaliland.—Jibuti.

British Somaliland.—Berbera.

Italian Somaliland.—Mogadiscio.

Kenya.—Mombasa.

Zanzibar.—Zanzibar.

Tanganyika.—Dar-es-Salaam.

Seychelles.—Victoria.

Mauritius.—Port Louis.

Madagascar.—Tamatave, Majunga.

Portuguese East Africa.—Mozambique, Beira, Lourenço Marques.

Union of South Africa.—Durban, East London, Port Elizabeth, Cape Town.

Reports had not been received in time for distribution from—

British India.—Rangoon.

Dutch East Indies.—Menado.

Week Ended Saturday, August 21, 1926

Maritime towns	Plague		Cholera		Smallpox

UNITED STATES PUBLIC HEALTH SERVICE

HUGH S. CUMMING, *Surgeon General*

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain: (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them.

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS. Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

PUBLIC HEALTH REPORTS

VOL. 41 SEPTEMBER 24, 1926 NO. 39

PUBLIC HEALTH IN STATE CONSTITUTIONS

By JAMES A. TOBEY, Lecturer on Public Health Law, Massachusetts Institute of Technology, Cambridge, Mass.

Provisions pertaining to public health may now be found in the existing constitutions of 9 of our 48 States. In most instances these sections require the legislature to establish a State board of health, though a few deal with the powers of the legislature regarding local health administration. In only one case, that of Texas, is the creation of the State board of health (and vital statistics) by the legislature made permissive and not mandatory. In a few States there are also provisions in the constitutions concerning the practice of medicine.

A State constitution is the supreme law of the State, subject only to such legal limitations as may be expressed or implied in the Federal Constitution, which enumerates the powers which have been granted to the National Government. The State constitution is more in the nature of a limitation of powers, because all things not denied in this instrument may be performed by the State, and all matters required therein must be done by the State, or by the citizens thereof, as the case may be.

The care of the public health is, under our form of government, entrusted primarily to each of the individual States, which is supreme so far as the health of its own people is concerned. This duty forms a part of the police power of the State, a power possessed before the National Government was formed and not relinquished to the United States then or subsequently. It is, in fact, the inherent responsibility of the State to promote and protect the health of its inhabitants, a duty which can not be refused or given up. This is so whether there are health provisions in a State constitution or not.

Public health need not be specifically mentioned in a State constitution in order to give the State power over this important function of government. It is useful, however, to require in this document that a State health organization be created, or to set forth in general terms the duties of the legislature with respect to public health. From the standpoint of government it is questionable policy for the State constitution to go into details as to administrative procedure in this connection. Such details will, moreover, be found in only one State constitution, that of Louisiana, where the composition of the

State board of health is presented in a most minute manner. Such matters should be left to the discretion of the law-making body of the State, the legislature; for, with the advancement of science, it may be found expedient to change the type of organization from time to time. A statute may be altered much more readily than may a constitution It is, of course, the privilege of the people to place administrative details in their organic law, but it is a poor principle, nevertheless.

In the following pages will be given those portions of the nine State constitutions which have to do with the public health. There are, obviously, many other parts of State constitutions which affect public health, either directly or indirectly Thus in Georgia it was recently held by the supreme court of that State that, although the constitution authorizes the collection of county taxes for "necessary sanitation," a State law permitting taxation to pay registrars of vital statistics fees for such statistics is unconstitutional, as "necessary sanitation" does not include the collection of such statistics.[1]

In the quotations from the State constitutions given below it will be noted that in only three instances do the particular articles of the respective constitutions bear the title of "Health" or "Public Health" In all other instances the health provisions are contained under other sections of the constitutions, such as those referring to "Legislative department," "Administrative officers and boards," "Municipal corporations and police regulations," "General provisions," or "Miscellaneous" The most succinct statement is given in the California constitution, while the longest and most detailed statement appears in the constitution of Louisiana. The State board of health is the subject of provisions in the constitutions of California, Delaware, Florida, Louisiana, Oklahoma, Texas, and Washington; county (or parish) boards are dealt with in those of Florida and Louisiana; and local boards of health are mentioned in the constitutions of Delaware, Louisiana, and South Carolina, the last named not dealing with State organization at all. In each of these last three States the local health authorities are stated to be subordinate to the State officials. The practice of medicine is the subject of provisions in the constitutions of Louisiana, Texas, and Washington The health section in the Wyoming constitution is the most general in scope. It is also worth noticing that while the Oklahoma constitution requires the creation by the legislature of a State board of health the legislature has actually set up an organization consisting of a single commissioner in charge of a department of health.[2]

[1] Smith vs State, 129 S E. 542. [2] Comp L of 1909, sec 340

CALIFORNIA

Constitution of 1879, Article XX (Miscellaneous)

Section 14 The legislature shall provide by law for the maintenance and efficiency of a State board of health.

DELAWARE

Constitution of 1897, Article XII (Health)

The general assembly shall provide for the establishment and maintenance of a State board of health, which shall have supervision of all matters relating to public health, with such powers and duties as may be prescribed by law; and also for the establishment and maintenance of such local boards of health as may be necessary, to be under the supervision of the State board, to such extent and with such powers as may be prescribed by law.

FLORIDA

Constitution of 1885, Article XV (Public Health)

Section 1· The legislature shall establish a State board of health and also county boards of health in all counties where it may be necessary

Section 2 The State board of health shall have supervision of all matters relating to public health, with such duties, powers, and responsibilities as may be prescribed by law [5]

Section 3 The county boards of health shall have such powers and be under the supervision of the State board to such extent as the legislature may prescribe.

LOUISIANA

Constitution of 1921, Article VI (Administrative Officers and Boards)

Section 11 The legislature shall create for the State and for each parish and municipality therein boards of health and shall define their duties and prescribe their powers The parish and municipal boards of health shall be subordinate to the State board of health. The State board of health shall be composed of a president, who shall be designated as State health officer, and eight members, one from each congressional district as at present constituted, five of which members shall be duly qualified and registered physicians, and the three others shall have such qualifications as shall be prescribed by the legislature The governor shall, by and with the advice and consent of the senate, appoint the president and members of the State board of health

Section 12 The legislature shall provide for the interest of State medicine in all of its departments, for the protection of the people from unqualified practitioners of medicine, dentistry, veterinary medicine, and pharmacy; for protecting confidential communications made to practitioners of medicine and dentistry and druggists by their patients and clients while under professional treatment and for the purpose of such treatment; for the protection of the people against the sale, barter, gift, and use of injurious or adulterated drugs, foods, and drinks, and against any and all misbranding and adulteration of the general necessaries of life of whatever kind or character [4]

---

[5] It has been held in Logan v Childs (51 Fla 233, 41 So 197) that this section has no application when the board declines to interfere with a municipal ordinance.

[4] Article 296 of the 1913 constitution had the following provision.

"The general assembly shall create for the State and for each parish and municipality therein boards of health, and shall define their duties and prescribe the powers thereof The State board of health shall be composed of representative physicians from the various sections of the State "

OKLAHOMA

Constitution of 1907, Article V (Legislative Department)

Section 39 The legislature shall create a board of health, board of dentistry, board of pharmacy, and pure food commission, and prescribe the duties of each. All physicians, dentists, and pharmacists now legally registered and practicing in Oklahoma and Indian Territory shall be eligible to registration in the State of Oklahoma without examination or cost.

SOUTH CAROLINA

Constitution of 1895, Article VIII (Municipal Corporations and Police Regulations)

Section 10· Boards of health It shall be the duty of the general assembly to create boards of health wherever they may be necessary, giving them the power and authority to make such regulations as shall protect the health of the community and abate nuisances.

TEXAS

Constitution of 1876, Article XVI (General Provisions)

Section 31: The legislature may pass laws prescribing the qualifications of practitioners of medicine in this State and providing for the punishment of persons for malpractice, but no preference shall ever be given by law to any schools of medicine.

Section 32: The legislature may provide by law for the establishment of a board of health and vital statistics, under such rules and regulations as it may deem proper

WASHINGTON

Constitution of 1889, Article XX (Public Health and Vital Statistics)

State board of health: 1 There shall be established by law a State board of health and a bureau of vital statistics in connection therewith, with such powers as the legislature may direct

Medicine and surgery. 2. The legislature shall enact laws to regulate the practice of medicine and surgery and the sale of drugs and medicines.

Same, Article II (Legislative Department)

Section 35· The legislature shall pass necessary laws for the protection of persons working in mines, factories, and other employments dangerous to life or deleterious to health; and fix pains and penalties for the enforcement of same.

WYOMING

Constitution of 1889, Article VII (Education)

Section 20: As the health and morality of the people are essential to their well being, and to the peace and permanence of the State, it shall be the duty of the legislature to protect and promote these vital interests by such measures for the encouragement of temperance and virtue, and such restrictions upon vice and immorality of every sort, as are deemed necessary to the public welfare.

A STUDY OF ILLNESS IN A GENERAL POPULATION GROUP[1]

Hagerstown Morbidity Studies No. I: The Method of Study and General Results

By EDGAR SYDENSTRICKER, Statistician, United States Public Health Service

In a previous paper a report was given of the general results of a morbidity study in Hagerstown, Md[2] These results were provisional, since they were based on a preliminary tabulation.

In the present communication a more precise and complete statement is made of—

1. The scope of the study and the method of observation;
2. The general character of the results obtained,
3. The procedure employed in classifying illnesses according to cause,

And some of the general results are given of a final tabulation of the data collected, including—

1. The incidence of illness and the causes thereof as observed over a period of 28 months;
2. The incidence of certain *acute diseases* in so far as they were observed, whether they were the sole cause or were complicating conditions or sequelæ of a given illness,
3. The proportion of *persons* among whom certain diseases or conditions were incident or prevalent during the period

In later papers it is planned to present other phases of the study.

SCOPE OF THE STUDY AND METHOD OF OBSERVATION

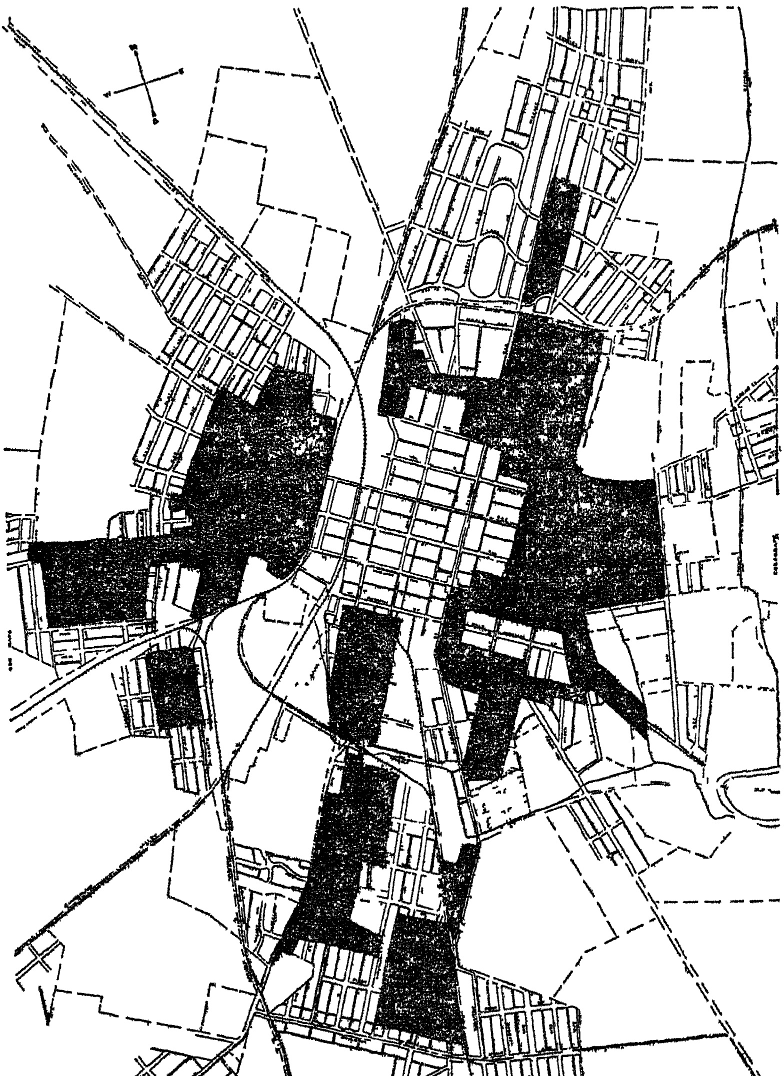
A brief description of the scope and method of the study was given in the preliminary report, but for the sake of completeness and greater precision, as well as to afford the opportunity of making certain addenda, this description is somewhat revised and amplified here.

Location of study.—The city of Hagerstown was selected for this study partly because certain facilities were already afforded by the location there of a health demonstration and partly because it was a fairly typical small city in that part of the eastern section of the country which had not been influenced greatly by recent immigration At the time when the study was made Hagerstown had a population of about 30,000 (29,878 estimated as of February 1, 1923, the mid-date of the period of observation) In 1920, 93 per cent of its population were native white and 88 per cent were native white of native parents. The foreign born comprised less than 2 per cent, and 5 per cent were colored. Of the total population 10 years of

[1] From the Office of Statistical Investigations, United States Public Health Service.

[2] The Incidence of Illness in a General Population Group. Pub Health Rep. Feb 13, 1925, 40, 279-291. (Reprint No 989)

age and over, only 3 per cent were classed illiterate, and of the native white of the same ages only 2 per cent were classed as illiterate. No large or predominant industry is located in Hagerstown, the chief industries being those incident to the requirements of the surrounding



Plat of Hagerstown showing scattered areas in which the population was observed for incidence of illness from Dec 1, 1921, to Mar 31, 1924, by U S Public Health Service investigators

area—retail and wholesale trade, a number of small factories, and transportation. Among the wage-earning group, railroad work probably predominates, the shops of the Western Maryland Railway being situated there.

Scope—The study was planned to include between 1,500 and 2,000 families, and the sections of the city in which the observations were to be made were selected upon two grounds, namely, (1) representativeness of different economic classes, and (2) convenience for repeated visiting The accompanying plat of the incorporated city shows the sections selected Only white persons were included, since the number of negroes was too small to yield comparable results.

In the final tabulation of the results the observations made in 1,815 households were included These households contained 8,587 persons for whom morbidity information at one or more canvasses was secured The actual number of households visited was somewhat larger, the discarded households being of two kinds—those which moved away from the city or to some section of the city inconvenient for the field assistants to visit and those from which only unsatisfactory information could be secured. The proportion of the latter was small; in fact, the cooperation given by the families of all economic classes was very satisfactory and gratifying. As will be explained later, the data approximate a continuous record for 28 months. A certain amount of change necessarily occurs in an ordinary population of this size, however. As stated above, 8,587 persons were included in the study, but the maximum population in any one month was 7,572. Obviously, births and deaths affected the population, and sons and daughters were married, sometimes living with a parent temporarily and later leaving the household for some part of the city not being canvassed. Occasionally no one could be found at home or the family was away on a vacation for a month or two in the summer. The following table shows, however, that 90 per cent of the persons were observed for one year and 50 per cent for 26 of the possible 28 months.

Per cent of persons observed for specified number of months in the Hagerstown morbidity study

Months under observation	Persons under observation specified number of months	
	Number	Per cent of total
28 months	3,202	37 3
26 months or more	5,140	49 8
24 months or more	5,787	67 4
18 months or more	6,824	79 5
14 months or more	7,528	87 7
12 months or more	7,794	90 8
9 months or more	8,085	94 2
6 months or more	8,340	97 1
4 months or more	8,431	98 2

When the number of persons born or dying in the household which was observed 26 months or more is added we find that 63 per cent of the total persons of record were in the population classed as "Under observation 26 months or more".

If we express this total "exposure" in terms of persons for one year our population consists of 16,517 "years of exposure," of which 8,001 were for males and 8,516 for females This is the *numerical* equivalent of a population of 7,079 persons observed continuously for 28 months, or an average monthly population of the same size.[3]

Sex and age distribution of the population —In selecting the population for study, persons living in families were chosen; and in selecting the families for study, some preference was given to those with children. As a result, the observed population has a greater percentage of children under 15 years of age and slightly fewer young adults from 20 to 35 years of age than the entire city. The percentage distribution of the observed population is compared with the total Hagerstown population in the table below:

Percentage distribution of Hagerstown population and of the observed population

Age group	Hagerstown, census of 1920	Observed population 1921–1924	Difference + or −
Total	100 0	100.0	
0–4	10 7	11 0	+0 3
5–9	10 2	13 0	+2 8
10–14	8 7	10 6	+2 1
15–19	8 4	8 6	+0 2
20–24	9 3	7 0	−2 3
25–34	17 9	15 3	−2 6
35–44	13 6	13 5	−0 1
45–64	16.3	16 0	−0.3
65 and over	4 8	5 0	+0 2

These differences are not great enough to prevent the observed population from being typical of the whole, an indication not without interest in itself since it suggests that in a city of this type there is a comparatively small number of unattached persons, and that family groups constitute almost the entire population. The differences shown in the table are so slight that if the total illness rate for persons of known age in the observed population is adjusted according to the Hagerstown population the rate is lowered less than 3 per cent. In fact, if we adjust the rate for sex and age to the population of the United States it becomes 1054 per 1,000 as against a crude rate of 1081, a difference of only 2 per cent.

Method.—The method of observation and recording the results may be described briefly as follows:

[3] This figure is somewhat smaller than that (7,200) used in the preliminary report because of the discarding of some families, as explained above.

(1) A preliminary house-to-house survey was made by members of the staff of the Office of Statistical Investigations in November, 1921, in the several sections selected, in the course of which the population of these sections was enumerated and records were made (*a*) for each individual, relating to color, sex, and age, past occurrence of certain contagious diseases and present acute or chronic diseases or ailment, and (*b*) for each household relating to its general economic status, sanitary condition, method of excreta disposal, and water and milk supplies.

(2) This survey was followed by a series of 16 canvasses, each household being visited by a trained field assistant at intervals of from six to eight weeks At each visit a history of the incidence of sickness in the family since the preceding visit, with a statement of the date of onset, duration, extent of disabling effects, and attendance of physician, was obtained from a relatively responsible informant, usually the housewife

(3) In addition, other sources of information were regularly and systematically utilized in obtaining the record of disease prevalence, as follows: (*a*) Weekly records of absence from school, specifying the nature of the illness whenever illness was the cause so far as the teacher could ascertain it; (*b*) reports of all cases treated in the various clinics maintained in conjunction with the Washington County Health Demonstration, all of the clinics being participated in by local physicians; (*c*) reports of notifiable diseases from practicing physicians; (*d*) reports of district nurses; (*e*) data collected in field investigations of child hygiene by the United States Public Health Service in cooperation with the Washington County Health Demonstration.

(4) For all cases attended by physicians the statements made by the informant as to the nature or cause of illness were submitted to the physicians concerned for review and correction.

GENERAL DISCUSSION OF THE NATURE OF THE RESULTS OBTAINED

As it was pointed out in the preliminary report, the result of these canvasses is not, of course, a complete record of all of the ill health prevalent in this population during the period of observation nor even an accurate statement of the causes of all the attacks of disease which were recorded Such a record was impracticable for so large a population of this kind, and no false hopes of obtaining it were indulged in Furthermore, it must be obvious from clinical experience as well as from considerations of a practical kind that the full extent of ill health and its specific nature can not be ascertained by any one method. Properly conducted physical examinations, supplemented by the necessary laboratory findings, will yield certain indispensable

indications of the existence and the net results of various diseases and conditions, but they will not tell the whole story. A carefully obtained history, for each individual, of previous health, incidence of disease, occurrence of various symptoms, and exposure to certain possibly relevant conditions will add to the picture Of undoubted importance is a period of observation during which the reactions of the individual under ordinary as well as specific circumstances are recorded; this record may be of the occurrence of various symptoms and of the extent to which the subject is affected-- whether only slightly ill, or more or less continuously "below par," or unable to engage in his usual activities, or disabled for long periods, or dying The detail and accuracy with which these observations are made depend, naturally, upon the means employed.

Our study was of the nature of the third method mentioned above, namely, *a series of observations which was directed as specifically as possible to the illnesses which occurred among a population during the period chosen.*

Now, it is evident that the length of interval between inquiries is one important determinant of *how much* sickness and what kinds of sickness will be recorded A weekly inquiry will elicit information on more slight ailments than a monthly inquiry, and an inquiry made every six or eight weeks will fail to obtain information on many ailments of very short duration or of several days' duration but accompanied only by slight discomfort. From previous experience in sickness surveys and continuous morbidity records and disability records of industrial employees we were led to believe that the intervals between visits chosen for the present study would probably yield a fairly accurate record of *real illnesses.*

As a matter of fact, less than 5 per cent of the illnesses of exactly stated durations recorded in our study were one day or less in duration. Nearly 80 per cent were three days or longer, and 60 per cent were eight days or longer in duration [4] Approximately 40 per cent were not only disabling but caused confinement to bed. It is evident, therefore, that in the main the illnesses recorded were more than trivial in their character, in spite of the fact that in some instances mere symptoms were given as diagnoses The incidence of acute attacks of specific and generally recognizable diseases has been, we feel, recorded with a satisfactory degree of completeness. On the other hand, the incidence of mild attacks, as, for example, of coryza, and of slight disorders and even of serious conditions when such conditions were not accompanied by noticeable symptoms, is probably incomplete and in many instances inaccurate in spite of the fact

[4] The results of this study relating to duration of cases of illnesses will be presented and discussed in a later paper

that a record of 28 months was obtained for the same individuals. Cases attended by physicians may be said to be quite complete.[5]

The question properly may be asked: Exactly what is meant by "illness"? The question is hard to answer with a precise definition. In the first place, the records of "illness" obtained in this study were of illnesses as reported by the household informant (usually the wife) either as experienced by herself or as she observed them in her family, the definition of the term thus can not be refined any further than the common understanding of the word In the second place, the records as obtained were of *attacks* rather than illness in the sense of ill health As will appear later, of those persons affected with some chronic condition, only those who suffered ill effects of this condition *during the period* were recorded as having this condition. It is undoubtedly true that had we employed this method of study over a period longer than 28 months more conditions of this nature would have been brought to light, since the factor of time is a fundamental one in recording and interpreting morbidity. At the same time it must be evident that there is a period beyond which additional observation of this kind will not yield much additional information, when, for practical purposes, the "law of diminishing returns" renders further expenditure of effort and patience unprofitable for the purpose in mind.

The reader is cautioned against putting too fine a point on the definition of illness as recorded in this series of observations. Perhaps it is sufficient simply to bear in mind that the chief aim of the study was a record of illnesses, as ordinarily understood, that were experienced by a population group composed of persons of all ages and both sexes, and in no remarkable respect unusual. This record, the first of its kind so far as we are aware, was regarded as desirable in order to give a picture of the sickness *incidence* in a general population group over a sufficiently long period of time to distinguish it from sickness prevalence as ascertained at a given instant in time by the cross-section method.

CLASSIFICATION OF ILLNESSES ACCORDING TO CAUSE

When the stage of classifying the illnesses according to cause was reached in the course of this study it was brought home to us that while a little knowledge is a dangerous thing the task of dealing with a little more knowledge was a very puzzling and troublesome thing. The chief difficulty lay in the selection of the primary cause of illness when several possible causes were observed. This difficulty has

[5] During the same period in which this study was made every absence of school children in Hagerstown was recorded, with such information relating to cause of absence as could be secured from the children, parents, and teachers The sickness rates for children in school based upon records obtained in house-to-house visits were compared with the rates based upon school records, with the result that the two rates for sickness lasting three days or longer were almost identical About 50 per cent of sicknesses lasting one day or longer and about 75 per cent of those lasting two days or longer were recorded in the house-to-house canvasses, but a larger proportion of the short-time absences from school were ascribed to "headache" and other symptoms.

been experienced, of course, in dealing with the so-called "joint" causes of death, and a more or less arbitrary statistical procedure has been developed. But in the case of our morbidity records it happened that for many individuals there was a series of observations covering some period of time, and this entire sickness history of an individual frequently had to be considered in determining the primary cause of a particular illness In other words, we were in the position of knowing a good deal more about these individuals than we would learn from the entries ordinarily made on a death certificate There were other difficulties, as well, but in dealing with them all it seemed to us that the primary purpose to be kept in mind was *the immediate cause of each specific illness* The prevalence of any disease or the reason or reasons for the ill health of the individual concerned was regarded as another, although often related, matter, to be determined for another purpose This we tried to do by adhering to the procedure outlined below

1 The term "illness" was rigidly interpreted as "a continuous period of sickness,"[6] regardless of complications, even though in some instances the coincident occurrence of two or more conditions seemed to be a matter of chance. Thus, a person who had grippe, measles, and chicken pox within one continuous period, i e, without a definite statement from the family that some time intervened between the separate conditions, would be credited with only *one illness*. A person with several chronic conditions contributing to a more or less continuous condition of illness was counted as sick only once, and one condition was considered the primary cause and the others contributory causes All respiratory illnesses were carefully edited to see that the same continuous sickness was not counted as two illnesses when due to what seemed to be *successive* or *progressive* conditions Thus a person might report a cold followed by pneumonia; this would be counted only once as pneumonia. Similarly, many combinations of respiratory conditions were reported, such as cold and bronchitis, bronchitis and tonsillitis, tonsillitis and influenza. All were counted as *one illness*, and that condition which, from the obtainable information, was chiefly responsible for this particular illness was considered the sole cause.

2. In the many cases in which more than one cause of an illness or attending condition was recorded the following general rules were followed in selecting the primary cause under which the illness was classified:

(*a*) The *first* cause in order of occurrence, applied largely to acute conditions with common complications, such as influenza and pneumonia, measles and otitis media, scarlet fever and nephritis.

(*b*) *Acute* conditions ordinarily were given preference over an attack of some chronic condition. Thus, in case of gripppe and chronic rheumatism, the grippe was considered primary.

[6] The annual incidence rate determined by our final tabulation was 51 per 1,000 less than in the preliminary tabulation, a difference due primarily to a more rigid conformance to this interpretation.

(c) The condition or disease *most specifically associated with the period of sickness* was preferred over a minor condition which preceded or accompanied it For example, tooth abscess and rheumatism; the latter was made primary. When it was difficult to determine the factual basis, the more serious condition was chosen

(d) The *more specific* cause was given preference over a statement of a symptom

(e) When none of the above rules could be applied, and the history of the individual gave no basis for decision, the condition mentioned first by the informant was made primary The number of such cases was relatively small

Rather frequently the informant mentioned more than one condition in telling about an illness, but when these conditions were in the nature of symptoms which simply amplified the information as regards a single cause of illness they were not tabulated as complications or contributory causes For example, a person may have reported indigestion and a headache as the cause of illness, but only the indigestion was counted. In other words, *symptoms* were not made contributory causes unless it seemed quite certain they represented a condition *separate* and *distinct* from the primary diagnosis. On the other hand, all specific conditions were tabulated, even though they were very frequently complications of the primary disease Thus, in the case of cold and indigestion, the cold was made primary, but the indigestion was tabulated as a complication.

The form of the classification used was the International List of Causes of Death, 1920 Revision. Some departures, dictated by considerations which we believe will be apparent to anyone more interested in the causes of illness than in a mere scheme of classification, were made from it, but in all the tables here presented the International List numbers are carried for definitive purposes.

THE INCIDENCE OF ILLNESSES CLASSIFIED BY CAUSE

The basic data used in this report are presented in Table 1. Here is shown the number of illnesses recorded during the 28 months, classified according to the sole or primary cause The principal specific causes are shown separately and also the totals for groups of diseases according to the International List of 1920 In the last two columns of the table are shown the number of times each disease was reported as a complicating or contributory cause of an illness. Thus if it is desired to know the number of times otitis media was the primary cause of illness the first three columns in Table 1 show that there were 117 illnesses due to this cause, 57 males and 60 females; but the last two columns in the table show that otitis media was present in an additional 19 illnesses of males and 30 illnesses of females, and the sum of the two numbers for males and the two for females gives, therefore, the total number of times otitis media was either a primary cause or a contributory cause of illness.

TABLE 1.—*Number of illnesses in which specified diseases or conditions were the sole or primary cause and the number in which each disease or condition was reported as a contributory cause in a canvassed population group of white persons in Hagerstown, Md., December 1, 1921–March 31, 1924*

Diseases and conditions causing illness (numbers in parentheses refer to those given in the International List of the Causes of Death, 1920)	Number of illnesses in which specified disease was the sole or primary cause			Number of illnesses in which specified disease was a contributory cause	
	Both sexes	Male	Female	Male	Female
Years of life exposed	16,517	8,001	8,516

Fractures, wounds, injuries (ind.) (183–188, 201, 202)	116	113	3	1	
Fractures, wounds, injuries (nonind.) (183–188, 201, 202)	373	177	196		2
Fractures, wounds, injuries (not stated) (183–188, 201, 202)	51	43	8		
Other external causes (165–174, 181–182, 189, 190–196)	32	17	15		
Ill-defined and unknown	168	74	94		2

[2] Includes rash, hives, and sores on body.

From the point of view of the frequency of illness from various causes, the rate per 1,000 persons is a much more comprehensible term, although as a single expression it can not afford the detail given in Table 1. In Table 2, therefore, is shown the annual illness

rate based upon our 28 months' experience It should be observed that this rate is computed in all instances by dividing the number of cases recorded by the "years of exposure."

TABLE 2.—*Morbidity from groups of causes and from certain specified diseases in canvassed population group of white persons of Hagerstown, Md, December 1, 1921–March 31, 1924*

Diseases and conditions causing illness (numbers in parentheses refer to those given in the International List of Causes of Death, 1920)	Annual rate per 1,000 persons observed		
	Both sexes	Male	Female
All causes	1,080.5	942.5	1,210.2
Total respiratory (excluding operations) (11, 97–107, 109, 31)	656.5	593.2	716.1
Influenza and grippe (11)	143.2	126.1	159.3
Pneumonia (all forms) (100, 101)	6.7	7.1	6.3
Pleurisy (102)	2.0	1.6	2.3
Diseases of pharynx (109)	65.7	58.4	72.6
Tonsillitis	28.5	24.1	32.5
Sore throat	31.0	27.9	33.9
Quinsy	3.0	3.5	2.6
Other diseases of pharynx	3.2	2.9	3.5
Diseases of larynx (98)	11.4	10.0	12.7
Laryngitis	5.8	3.1	8.2
Croup	5.3	6.7	4.0
Other diseases of larynx	.3	.1	.5
Hay fever and asthma (105, part of 107)	5.8	4.1	7.3
Tuberculosis, pulmonary (31)	3.1	2.0	4.2
Other diseases of respiratory system (including head colds, chest and bronchial conditions) (97, 99, 103, 107)	418.6	383.8	451.3
Tonsillectomy, adenoidectomy, or both	7.3	7.9	6.7
Other operations on throat and nasal fossæ	.5	.7	.2
Epidemic, endemic, and infectious diseases (1–42, except 11 and 31)	87.7	91.4	84.2

Paralysis (75)	1.5	1.1	1.9
Epilepsy (78)	.6	1.0	.2
Chorea (81)	1.2	.5	1.9
Neuralgia (part of 82)	6.1	2.5	9.5
Neuritis and sciatica (part of 82)	5.3	2.4	8.0
Headache (part of 82, part of 205)	15.1	8.0	21.7
Neurasthenia (part of 84)	11.0	2.9	18.6
Other nervous diseases (71–73, 76–77, 79, 80, 83, part of 82, part of 84)	2.7	2.4	2.9
Diseases of eye and annexa (85)	7.4	8.9	6.1
Diseases of ear and mastoid process (86)	10.9	10.1	11.6
Otitis media	7.1	7.1	7.0
Mastoiditis	.6	.9	.4
Other and unqualified diseases of the ear	3.2	2.1	4.2
Diseases of circulatory system (87–96)	18.3	14.1	22.3
Diseases of the heart (87–90)	10.1	6.4	13.5
Arteriosclerosis (part of 91)	1.2	1.4	1.1
Hemorrhoids (part of 93)	1.1	1.1	1.1
Adenitis (part of 94)	2.7	2.6	2.7
High blood pressure (part of 96)	1.2	.5	1.8
Other diseases of the circulatory system (92, 95, part of 91, 93, 94, and 96)	2.2	2.1	2.2

[1] Includes simple goiter only when it caused some illness in the period.

TABLE 2.—*Morbidity from groups of causes and from certain specified diseases in canvassed population group of white persons of Hagerstown, Md., December 1, 1921–March 31, 1924*—Continued

Diseases and conditions causing illness (numbers in parentheses refer to those given in the International List of Causes of Death, 1920)	Annual rate per 1,000 persons observed		
	Both sexes	Male	Female
Diseases and disorders of the digestive system (110–127, part of 108 and 205)	96.5	80.6	111.4
Ulcers of stomach and duodenum (111)	.7	1.2	.1
Indigestion and upset stomach (part of 112)	43.3	39.1	47.3
Biliousness (part of 205)	9.4	6.7	12.0
Stomach trouble, unqualified (part of 112)	7.6	7.0	8.1
Diarrhea −2 years (113)	4.5	4.5	4.6
Diarrhea +2 years (114)	8.2	7.2	9.2
Appendicitis (117)	5.1	3.2	6.9
Hernia (118a)	1.6	2.2	1.1
Intestinal disorders, including constipation (118b, 119)	2.2	1.6	2.8
Biliary calculi (123)	4.2	1.4	6.8
Cholecystitis (part of 124)	1.8	.4	3.2
Jaundice (part of 124)	2.7	2.2	3.2
Other and unqualified diseases of liver (part of 124)	1.7	.9	2.5
Other diseases of digestive system (110, 116, 126, 108 excluding teeth and gums)	3.3	2.7	3.8
Diseases of teeth and gums (part of 108)	7.5	5.9	9.0
Diseases of kidney and annexa (128–134)	11.0	7.1	14.7
Acute nephritis (128)	.5	.4	.7
Chronic nephritis (129)	2.6	2.0	3.2
Other and unqualified diseases of the kidney (131)	4.4	2.1	6.6
Cystitis and bladder trouble, unqualified (133)	2.5	1.7	3.2
Other diseases in this group (132, 134)	1.0	.9	1.1
Nonvenereal genito-urinary system (135–142)	11.1	1.1	20.4
Diseases of male organs (135–136)	.5	1.1	----------
Diseases of female genital organs (137–142)	6.0	----------	11.6
Menstruation (part of 141)	2.9	----------	5.6
Menopause (part of 141)	1.6	----------	3.2
Puerperal state (143–150)	23.9	----------	46.4
Abortion and stillbirth (part of 143)	2.0	----------	3.9
Confinements	19.6	----------	38.0
Other puerperal conditions (148–150)	2.3	----------	4.5
Diseases of skin and cellular tissue (part of 205,[1] 151–154)	17.6	20.6	14.8
Furuncle (152)	4.3	6.7	2.0
Abscess (153)	1.6	1.4	1.6
Impetigo contagiosa (part of 154)	1.5	1.5	1.4
Scabies and itch (part of 154)	1.4	1.9	.9
Other and unqualified skin conditions (part of 154 and 205)[1]	8.8	9.1	8.6
Diseases of bones and organs of locomotion (155–158, part of 205)	6.7	5.5	7.9
Lumbago, myalgia, myositis (part of 158)	3.0	3.2	2.7
Backache (part of 205)	2.2	.9	3.5
Other diseases of bones or locomotion (155, 156, part of 158)	1.5	1.4	1.6
Congenital malformations and infancy (159–163)	1.2	.6	1.6
Senility (164)	.8	.7	.9
External causes (165–203)	39.5	49.6	30.1
All poisonings (175, 176, 177)	2.8	3.5	2.1
Burns (178–179)	2.1	2.4	1.9
Fractures, wounds, injuries (ind.) (183–188, 201, 202)	7.0	14.1	.4
Fractures, wounds, injuries (nonind.) (183–188, 201, 202)	22.6	22.1	23.0
Fractures, wounds, injuries (not stated) (183–188, 201, 202)	3.1	5.4	.9
Other external causes (165–174, 181–182, 189, 190–196)	1.9	2.1	1.8
Ill-defined and unknown	10.2	9.2	11.0
Years of life exposed	16,517	8,001	8,516

[1] Includes rash, hives, and sores on body.

An illness rate of slightly more than one illness per person per year is indicated. This rate was somewhat higher than it would have been for two "normal" calendar years, for the reasons that the period of observation included nearly three winter seasons and only two summers and that in 1923 an outbreak of influenza occurred. At the same time it is far below what a record of *all* respiratory attacks

alone would show,[7] and very properly so, because the Hagerstown study was, as has been stated, a record of illnesses rather than of attacks that did not result in illness. The Hagerstown rate is about ten times the rate for illnesses causing absences from work among industrial workers (chiefly adult males) [8] for eight days or longer. The Hagerstown rate for males of all ages is more than twice the 1924 rate for illnesses causing absences of *two* days or longer among adult males employed in a group of establishments, while the Hagerstown rate for females of all ages is about 20 per cent higher than that for adult females employed in these establishments [9] When the higher illness rate among children, old persons as well as other persons not employed, who are included in the Hagerstown study, are taken into account, it would appear that the Hagerstown rate compares very favorably from the point of view of completeness with the records of illness incapacitating for two days or longer A more exact comparison, however, will be made in a later report when the records for persons of different ages are presented and discussed.[10]

The general picture of illness afforded by Table 2 is shown in graphic form in Figure 1. The relative importance from the point of *incidence*—not severity as measured by duration, incapacitation, fatality, or by other means—of the principal diseases and groups of diseases is indicated in such a way as to need no detailed comment, but a few general observations may be offered.

Doubtless it will be somewhat surprising that such diseases as tuberculosis, cancer, diseases of the heart, kidneys, etc., upon which so much emphasis is placed in public-health work, occupy such a low position in the list of diseases which cause illness. Upon this indication two comments suggest themselves: (1) That as *causes of illness* in a *general* population group, a group that has not been considered heretofore to the same extent as special groups of persons, these diseases are actually far less frequent than the ailments which most of us, who are not suffering from serious ill health, experience; (2) that the measure of the frequency of these diseases was, in this study, the extent to which they *manifested* themselves in illness; that is, our study was not an intensive physical examination nor an exhaustive survey of ill health. This observation is further supported

---

[7] Unpublished records of respiratory attacks among members of families of medical officers of the Army, Navy, and Public Health Service showed a rate of about 2,000 attacks per 1,000 persons. The rate among college students as reported by themselves for a six months' period was even higher, but it included many cases which ordinarily would not be noticed

[8] Frequency of Disabling Illnesses Among Industrial Employees Pub Health Rep., Jan 22, 1926, 41, 113-121. (Reprint No. 1060)

[9] From unpublished data in the Offices of Statistical Investigations and Industrial Hygiene, United States Public Health Service, upon which a report will be presented shortly.

[10] In Tables 1 and 2, under the heading of illnesses due to respiratory attacks, a large number (6,914 cases) are grouped under the subtitle "other diseases of respiratory system (including head colds, chest, and bronchial conditions)" During the second half of the period an effort was made to obtain more definite statements as to the nature of these attacks, the results of which will be presented in a later publication dealing with morbidity from respiratory diseases

by the evidence, which will be elaborated in a later paper, afforded by records of medical attendance which showed, for example, that all or practically all cases of tuberculosis, high-blood pressure, nephritis, cancer, etc , recorded were those which were attended by physicians during the period of observation.

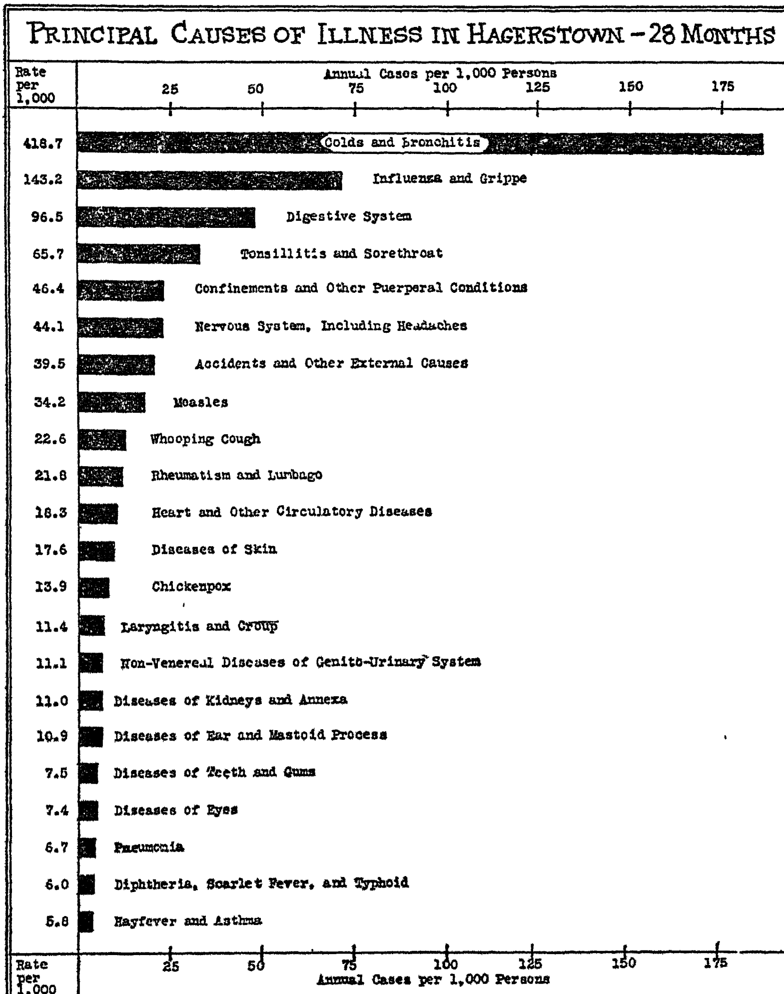

FIG 1

On the other hand, the general outline of the causes of illness in a fairly representative population afforded by Tables 1 and 2 seems to us to be extremely illuminating. It is shown that the causes of illness present an aspect quite different from that presented by the causes of mortality as we now record and classify mortality. Of

the total illnesses observed, we find the proportionate distribution according to broad groups of causes as follows:

Percentage distribution of illnesses in each broad disease group

General disease groups	Per cent of total illnesses
Respiratory	61.4
Epidemic, endemic, and infectious	8.1
General	2.0
Nervous system	4.1
Eye and annexa	.7
Ear and mastoid process	1.0
Heart and circulatory system	1.8
Digestive	8.9
Teeth and gums	.7
Kidneys and annexa	1.0
Genito-urinary (nonvenereal)	1.0
Puerperal	2.2
Skin	1.6
Bones and organs of locomotion	.6
External causes	3.7
Other	1.1

The fact that 61 per cent of the illnesses were due to respiratory diseases as against only 20 per cent of mortality in Hagerstown during the same period [11] is significant of the unsuitability of mortality statistics as any indication of the causes of morbidity. On the other hand, the fact that 35 per cent of the deaths as against 2.8 per cent of the illnesses were due to diseases of the circulatory system and kidneys and annexa is equally significant of the unsuitability of illness statistics (when cases of relatively short duration and slight severity are included) as indices of the causes of contemporaneous mortality. A relationship between morbidity and mortality exists, of course, but it is intricate and variable; the experience here presented confirms a wise dictum that no ratio between morbidity and mortality may be assumed for the great majority of diseases without a knowledge of their fatality.

INCIDENCE OF CERTAIN DISEASES AS REVEALED BY ILLNESS

Having clearly in mind the fact that the "statistical unit" in our study is an illness lasting approximately three days or longer, and having ascertained as best we could the causes of these illnesses and classified them accordingly, we may next consider the data as records of the incidence and prevalence of specific diseases.

It is obvious that the value of the observations in affording evidence on these important points must vary according to diseases in

[11] Incidence of illness in a General Population Group Pub. Health Rep., Feb. 13, 1926, 40, 279-291. (Reprint No 989.)

proportion to the extent to which an attack of a disease results in illness of that degree of severity which was recorded. Thus, many attacks of "colds" certainly were not recorded because only those resulting in "illnesses," according to the definition of the term, were observed. On the contrary, it is quite certain that a very much larger proportion of the cases of whooping cough were noticed. This suggests a point of refinement, however, that morbidity statistics are far from having attained, but which is well to keep in mind if one wishes to put data of the sort we are dealing with to uses involving rather fine shades of interpretation. It is reasonable to say, we believe, that the Hagerstown study affords a fairly complete indication of the incidence of most diseases occurring among a general population group the attacks or effects of which were severe enough to produce the condition of sickness.

With these limitations before us, two tables are presented for consideration

One (Table 3) shows the *annual* incidence rates for a number of acute diseases and diseases which manifested themselves in a more or less acute form, either as primary or as contributory causes of illness. It will be observed at once that some of the diseases are rather poorly defined, since they are grouped under general titles. This means that, while the information secured was sufficiently accurate to permit of a general classification as to their nature, it was not specific enough to warrant a very definite designation as to the exact disease or condition involved. For the great majority of diseases included in Table 3, however, we feel that the specific classifications employed are justified by the information secured.

The rates in Table 3 require no particular comment. They are of unusual interest, it is believed, because they represent a rather extended and intensive series of observations upon a fairly typical population. For some diseases the rates will possess somewhat permanent value as a basis for comparison with other morbidity studies of a similar kind; for others, such as measles or whooping cough, the rates are characteristic only of the particular period in which they occurred.

TABLE 3.—*Incidence of acute attacks of certain diseases resulting in illness during a 28 months' period in a general population group in Hagerstown, Md.*

Diseases and conditions causing illness (numbers in parentheses refer to those given in the International List of Causes of Death, 1920)	Number of cases			Rate per 1,000 years of exposure		
	Both sexes	Males	Females	Both sexes	Males	Females
Acute respiratory:						
Influenza and grippe (11)	2,382	1,014	1,368	144 21	126 73	160 64
Pneumonia, all forms (100-101)	144	75	69	8 72	9 37	8 10
Pleurisy (102)	38	16	22	2 30	2 00	2 58

Abscess (153)	31	12	19	1 88	1 50	2 23
Impetigo contagiosa (part of 154)	25	13	12	1 51	1 62	1 41
Scabies and itch (part of 154)	24	16	8	1 45	2 00	.94
Sores (part of 205)	67	36	31	4 06	4 50	3 64
Hives and rash (part of 205)	48	21	27	2 91	2.62	3 17
Other and unqualified skin conditions (part of 154)	49	25	24	2 97	3 12	2 82

In Table 4 an entirely different phase of morbidity is presented. This table represents an attempt to answer the question, How many *persons* were affected by certain diseases and conditions of a more or less continuing or chronic nature? Here, again it must be kept in mind that only those chronic conditions were revealed which manifested themselves in illness or definitely morbid effects as a result of the disease or condition during the period of observation. It is evident, of course, that observations such as these can not yield the same kind of results as a physical examination of each individual. Latent or incipient diseases and conditions that did *not* manifest themselves in morbid effects obviously do not appear in the rates

shown in Table 4 It is believed, however, that nearly all of the more serious of these diseases and conditions are portrayed While the cases recorded of venereal diseases, for example, are probably too low—although we have no comparable data to judge by—the rate for active cases of tuberculosis, to cite another instance, is just about what we would expect in a population and under conditions of the kind observed The facts that two-thirds of the persons were under observation for at least two years and that nine-tenths of them were observed for at least one year by a competent field assistant who took advantage of the opportunity to become fairly well acquainted with every family, should also be considered in appraising the completeness of the information collected and the accuracy of the rates in this table In fact, we are inclined to place slightly more dependence upon the data shown in Table 4 than upon the records of not serious attacks of some of the more acute diseases shown in Table 3.

TABLE 4 —*Prevalence of certain chronic conditions resulting in illnesses during a 28 month's period in a general population group in Hagerstown, Md*

Diseases or conditions (numbers in parentheses refer to those given in the International List of Causes of Death, 1920)	Number of persons reporting specified conditions			Rate per 1,000 individuals observed		
	Both sexes	Males	Females	Both sexes	Males	Females
Tuberculosis, pulmonary (31)	49	15	34	5.71	3.60	7.69
Tuberculosis, nonpulmonary (33-36)	11	4	7	1.28	96	1.58
Venereal diseases (38-40)	31	6	25	3.61	1.44	5.65

ACKNOWLEDGMENTS

The continuous field observations upon which the foregoing report is based were made by the following assistants: F. Ruth Phillips Mrs. Mary King Phillips, Louise Simmons, Mrs. Clara Bell Ledford, Clarice Buhrman, and Mrs. Alcesta Owen, under the immediate supervision of Passed Asst. Surg. R. B. Norment, jr., Acting Asst. Surg. A. S. Gray, and, later, Surg. C. V Akin.

In the analysis of the data I am especially indebted to Associate Statistician S. D. Collins and Assistant Statistician Dorothy G Wiehl, and other members of the statistical staff, as well as to several officers of the Public Health Service for constant advice on medical points.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Compact Rapid Sand Filters of Washington. Philip O. MacQueen, United States assistant engineer, Washington, D. C., district *Water Works Engineering*, vol. 79, No. 12, June 15, 1926, pp. 777–778 and 797–802. (Abstract by C. C. Ruchhoft.)

The rapid sand filtration plant of Washington, D C , which will be completed in 1927, is described The plant, with a capacity of 80,000,000 gallons per day, is located near the Dalecarlia 100,000,000 gallon raw-water reservoir. A 2,400 k hydroelectric plant, using surplus water from the raw-water conduits, will furnish power for pumping the filtered water. A control chamber near the reservoir has channels for the raw, treated, settled, and filtered water and is arranged to permit very flexible operation. The chemicals are applied in the control chambers. Two mixing basins, 80 feet square and 18 feet deep and fitted with baffles of the around-the-end type, providing a total travel of 1,600 feet per basin, are arranged to be operated in series or parallel. There are two settling basins, each 333 feet long by 150 feet wide and from 12 to 17 feet deep. Each basin is provided with a light concrete baffle wall, which causes the water to flow the length of the basin and return to a point opposite the influent. With the basins in parallel at the rated capacity of the plant, the settling period will be three hours and the velocity 3 feet per minute. The filter building has 20 filters 54 by 31 feet and 15 feet deep, with 18 inches and 30 inches of gravel and sand, respectively. The strainer system will be the new open wooden slat type. The filtered water flows to a 15,000,000-gallon covered concrete reservoir, from where it is pumped to the high service reservoirs in the city. The plant is arranged so that the depth of water in the filtered-water reservoir regulates the rate of the filters. The

pumping station contains nine pumps of the horizontal volute type driven by synchronous-type motors

Sterilization of Water. Ryukichi Joh *Journal of the Public Health Association of Japan*, vol. 2, No 4, April, 1926, pp. 4–6. (Abstract by E. C Sullivan.)

The use of bleaching powder was first introduced in Kagawa Prefecture in 1912 as an experiment, and subsequently it was used extensively in 1919 throughout dysentery-stricken areas in the prefecture Of the various methods for the chemical sterilization of drinking water practiced at present, chlorination is the best in every respect

The complaints of people against the use of chlorine when bleaching powder has been thrown into wells, due to odors and turbidity caused by the production of carbonate of lime, can be avoided by the use of chlorine in the form of hypochlorous acid An additional advantage is that hypochlorous acid is stronger than the same quantity of bleaching powder. It can be prepared any time, at any place, and in an easier way than bleaching powder

Hypochlorous acid can be prepared by placing bleaching powder and washing soda in a jar in the proportion of 20 parts of water, 1 of bleaching powder, and 2 of sodium carbonate, and stirring well until the soda is dissolved and floating substances are deposited.

If the solution formed is left standing for some time, the carbonate of lime will be deposited. The cleared liquid is then decanted, which is an easier and simpler method than making bleaching powder into a milky liquid. While its use brings no apparent change to the well water, its germicidal power is much stronger than that of bleaching powder.

Sand Flies and Sand-Fly Fever in the Peshawar District. Lieut. Col. T. C. McCombie Young, Capt. A. E. Richmond, and Assistant Surgeon G. R. Brendish. *Indian Journal of Medical Research*, vol 13, No. 4, April, 1926, pp. 961–1021. (Abstract by A. W. Fuchs.)

The investigations of the commission on sand-fly fever in the Peshawar District were largely concentrated on an endeavor to ascertain the breeding grounds of *P. papatasii.* Figures on hospital admissions indicated that immunity to sand-fly fever increases with length of residence. A dry season hastens the appearance of the sand fly as well as the seasonal peak of incidence of the disease. In 1923 and 1924 the number of British troops hospitalized on account of sand-fly fever rose to 11 per cent of the total monthly strength in June and continued at a high level through the two months of prevalance.

Some of the conclusions reached were the following: (1) Topography, sanitation in the vicinity of barracks, proximity of irrigation water and of bazaars appear to have little influence on sand-fly infestation of barracks, (2) on emerging from the pupa case in the earth cracks of the breeding grounds the female sand fly waits some hours till the chitin of the body hardens, takes shelter in a shaded earth crevice during daylight, feeds and is fertilized within 36 hours, remains in houses for 60 to 84 hours, and returns to the breeding grounds where eggs are laid within 108 hours, eggs hatch after a month or more, (3) *P papatasii* breed close to habitations in slightly moist organic matter lying in hollows in broken ground and nullahs, near a crack or crevice; for experimental breeding an earthenware pot filled with such materials is suitable, (4) no confirmation could be obtained of Whittingham's observation as to *Leptospira* as the possible causative agent of sand-fly fever; (5) sand-fly fever is a distinct disease entity, not a modified form of dengue, although the manifestations vary to a very large extent; (6) for personal prophylaxis a citronella-camphor mixture applied to a net has a protective influence as a repellant. On account of the cost and the practical difficulties, fumigation of barracks rooms is not practicable.

DEATHS DURING WEEK ENDED SEPTEMBER 11, 1926

Summary of information received by telegraph from industrial insurance companies for week ended September 11, 1926, and corresponding week of 1925 (From the Weekly Health Index, September 15, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Sept 11, 1926	Corresponding week, 1925
Policies in force	63, 960, 000	60, 986, 892
Number of death claims	9, 963	8, 782
Death claims per 1,000 policies in force, annual rate	8. 1	7. 5

Deaths from all causes in certain large cities of the United States during the week ended September 11, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, September 15, 1926, issued by the Bureau of the Census, Department of Commerce)

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

Wisconsin	8	106	34		901		5	146	3	11

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended September 4, 1926, 38 States reported 819 cases of diphtheria For the week ended September 5, 1925, the same States reported 835 cases of this disease Ninety-six cities, situated in all parts of the country and having an aggregate population of more than 29,600,000, reported 429 cases of diphtheria for the week ended September 4, 1926. Last year for the corresponding week they reported 392 cases. The estimated expectancy for these cities was 559 cases. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles—Thirty-seven States reported 626 cases of measles for the week ended September 4, 1926, and 268 cases of this disease for the week ended September 5, 1925. Ninety-six cities reported 142 cases of measles for the week this year and 123 cases last year.

Poliomyelitis.—The health officers of 38 States reported 119 cases of poliomyelitis for the week ended September 4, 1926. The same States reported 312 cases for the week ended September 5, 1925.

Scarlet fever.—Scarlet fever was reported for the week as follows: Thirty-eight States—this year, 752 cases; last year, 693 cases; 96

cities—this year, 295 cases; last year, 300 cases; estimated expectancy, 256 cases

Smallpox—For the week ended September 4, 1926, 38 States reported 119 cases of smallpox Last year for the corresponding week they reported 88 cases Ninety-six cities reported smallpox for the week as follows: 1926, 14 cases, 1925, 27 cases, estimated expectancy, 21 cases No deaths from smallpox were reported by these cities for the week this year

Typhoid fever—One thousand one hundred and eighty-two cases of typhoid fever were reported for the week ended September 4, 1926, by 38 States. For the corresponding week of 1925 the same States reported 1,118 cases of this disease Ninety-six cities reported 234 cases of typhoid fever for the week this year and 218 cases for the corresponding week last year. The estimated expectancy for these cities was 247 cases

Influenza and pneumonia—Deaths from influenza and pneumonia were reported for the week by 92 cities, with a population of about 29,100,000, as follows. 1926, 304 deaths, 1925, 397 deaths.

City reports for week ended September 4, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics It is based on reports to the Public Health Service during the past nine years It is in most instances the median number of cases reported in the corresponding week of the preceding years When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviations from the usual trend For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

The following table gives the rates per 100,000 population for 102 cities for the five-week period ended September 4, 1926, compared with those for a like period ended September 5, 1925. The population figures used in computing the rates are approximate estimates as of July 1, 1925 and 1926, respectively, authoritative figures for many of the cities not being available. The 102 cities reporting cases had an estimated aggregate population of nearly 30,000,000 in 1925 and nearly 30,500,000 in 1926. The 96 cities reporting deaths had more than 29,250,000 estimated population in 1925 and more than 29,750,000 in 1926. The number of cities included in each

group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, August 1 to September 4, 1926—Annual rates per 100,000 population, compared with rates for the corresponding period of 1925[1]

DIVISION OF SANITARY REPORTS AND STATISTICS

Asst Surg Gen B J LLOYD, *Chief of Division*

The PUBLIC HEALTH REPORTS are issued weekly by the United States Public Health Service through its Division of Sanitary Reports and Statistics, pursuant to acts of Congress approved February 15, 1893, and August 14, 1912

They contain (1) Current information of the prevalence and geographic distribution of preventable diseases in the United States in so far as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other communicable diseases throughout the world. (2) Articles relating to the cause, prevention, or control of disease. (3) Other pertinent information regarding sanitation and the conservation of the public health.

The PUBLIC HEALTH REPORTS are intended primarily for distribution to health officers, members of boards or departments of health, and those directly or indirectly engaged in or connected with public health or sanitary work. Articles of general or special interest are issued as reprints from the PUBLIC HEALTH REPORTS or as supplements, and in these forms are available for general distribution to those desiring them

Requests for and communications regarding the PUBLIC HEALTH REPORTS, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C.

The Public Health Service is unable to supply the demand for bound copies of the PUBLIC HEALTH REPORTS Librarians and others receiving the PUBLIC HEALTH REPORTS regularly should preserve them for binding, as it is not practicable to furnish bound copies on individual requests.

ADDITIONAL COPIES
OF THIS PUBLICATION MAY BE PROCURED FROM

EXPERIMENTAL STUDIES OF WATER PURIFICATION

I. DESCRIPTION OF EXPERIMENTAL WATER-PURIFICATION PLANT

By FREDERIC J MOSS, Assistant Sanitary Engineer, United States Public Health Service

In July, 1924, an experimental water-purification plant was put into operation on the grounds of the stream pollution investigations laboratory at Cincinnati, Ohio, and has been operated continuously since then up to the time of this writing, April 28, 1926 It is the purpose of this article to give a brief engineering description of this plant, which presents some interesting features and, it is believed, may serve as an example of the possibilities which exist for constructing highly efficient water-purification plants for small communities of less than 2,000 inhabitants

The primary object of constructing and operating this experimental plant was to provide a means whereby a detailed study could be made of the limits of raw-water pollution which are consistent with the production of effluents conforming to accepted standards of bacterial quality, having reference to water-purification plants of the type found along the Ohio River and on other similar inland river systems of the country serving as sources of purified municipal water supplies. Studies of stream pollution, which were begun actively by the Public Health Service in 1913, had shown the vital importance of establishing some scientific basis for fixing the permissible limits of pollution of streams at the various sources from which raw-water supplies are taken for purification. Prior to the construction of the experimental plant two series of observations bearing on this question had been made at selected groups of municipal water-filtration plants located in various parts of the Eastern and Middle Western States. The results of these observations [1] had indicated that a need existed for a further study of the problem under conditions subject to experimental control, such as are not obtainable at full-scale municipal plants, for obvious reasons. The experimental plant described in this article was designed chiefly with this purpose in view, though it also was intended for use in studying other problems having a bearing on the limitations in respect to bacterial efficiency existing in water-purification processes in general.

The construction of the experimental plant was authorized by the Surgeon General in December, 1922, as a result of the recommenda-

[1] For a description of these observations and a discussion of their results, see Reprint No. 737 from the Public Health Reports, Mar. 31, 1922, and Reprint No 987 from the Public Health Reports, Jan. 30, 1925.

tion of the consultants [2] in stream-pollution investigations. Following preliminary studies and the preparation of detailed plans and specifications, a contract was let in June, 1923, and the plant was constructed during the following autumn and winter [3] After a rather thorough series of preliminary tests, the plant was put into regular operation on August 1, 1924.

FEATURES OF DESIGN

The plant is of the rapid sand type, similar in its main features to most of the full-scale plants found along the Ohio River and on other inland streams of the United States It comprises the usual sedimentation basin, with means for coagulating the water chemically before delivery to the basin; two rapid sand filters of the gravity-flow type; clear-water storage facilities; and a continuous-feed chlorinator. Its output capacity at a normal rate of filtration (2 gallons per square foot of filter surface per minute) is 160,000 gallons per 24 hours, which would be sufficient in amount to supply a community of 1,600 people with 100 gallons per capita daily. The plant actually is larger than some small community installations in active service.

EXPERIMENTAL FEATURES

Although every effort was made to have the plant conform to current practice in its design, in order that the results obtained from its operation might be fairly representative of those to be expected from full-scale plants of similar type, it exhibits some features, designed especially for experimental purposes, which are unusual to municipal plants engaged in the active service of supplying water to domestic consumers These features may be briefly indicated as follows:

1. Provisions for delivering to the plant a continuous supply of Ohio River water, domestic sewage, or clear dilution water, or mixtures of these components in any desired proportions, thus giving a raw water varying over a wide range in its composition, both physically and bacterially.
2. Parallel division of the plant into two independently functioning halves, which permits the making of parallel observations, under exactly similar conditions, with two different methods of treatment, applied continuously.
3 An unusual flexibility in the arrangement and interconnection of the various units, whereby any particular unit may be operated in conjunction with any other unit, or may be by-passed entirely, if desired.

---

[2] The consultants are Dr Stephen A. Forbes, Dr. Edwin O Jordan, Mr. Langdon Pearse, and Prof. Earle B. Phelps.

[3] The construction contract work was performed by F B Leopold, of Pittsburgh, with the Ferro-Concrete Construction Co., of Cincinnati, as subcontractor for the concrete and masonry work.

DESCRIPTION OF THE PLANT

In the text which follows the main features of each separate division of the plant will be described, particular attention being given to those features which are concerned more especially with its use for experimental purposes. Dimensions and capacities of the various units will be given wherever they bear on the design of the plant. In this connection reference is made to Figure 1, showing a general plan of the plant proper, and to Figure 2, containing a diagrammatic profile of the entire installation, including the river intake and raw-water force main, which are not shown in Figure 1

Intake—The intake, which is located in the Ohio River, differs considerably from that found in connection with the average large-scale installation, as the funds available for the work and the comparatively limited period over which it was expected to operate did not warrant extensive construction. A steel, screw-joint pipe, about 150 feet long, 30 feet of which is below the normal pool level [4] of the river, serves as the intake pipe. The lower end of this pipe is at an elevation corresponding to a river stage of 6 5 feet (Cincinnati Weather Bureau gauge), and the upper end of it is connected to the force main at an elevation corresponding to a river stage of about 60 feet. For use in priming the river water pump the lower end of the intake pipe is provided with a foot valve, and the connection to the force main is made with a check valve and by-pass connection. The intake pipe is provided with eight 4 by 3 inch tees located every 15 feet, each carrying an outstanding 3-inch hose valve and seven 4-inch gate valves inserted at mid-points between the hose valves. With this arrangement of valves, by connecting the pump suction with one of the hose valves, the discharge with the next higher hose valve, and closing the gate valve between these two connections, the intake pipe serves as a combined suction and discharge pipe for the river-water pump. The large number of hose connections and gate valves in the intake pipe are necessary because of the wide fluctuations in the stage of the Ohio River.

River-water pump—The river-water pumping unit comprises a two-stage centrifugal pump, with a 3-inch suction and a 2½-inch discharge, direct connected to a 15-horsepower induction motor, and has a capacity of 175 gallons per minute against a head of 150 feet. This unit is mounted on a small flat car equipped with two narrow-gauge trucks and is suitably housed for protection against the weather.

Parallel to and about 1 foot from the intake pipe is a narrow-gauge industrial track, supported on 6 by 6 inch stringers resting directly on small concrete piers spaced every 10 feet. The lower part of the

[4] Normal pool level corresponds to a river stage approximating 12 feet, as measured on the United States Weather Bureau gauge at Cincinnati.

track and intake pipe is laid on a grade of 18 5° and the upper part on a grade of 27.4°, the change in grade being made at an elevation corresponding to a river stage of about 28 feet The use of two grades was necessary in order that the track and intake pipe might conform to the slope of the river bank In order that the river-water pump may be level on both grades of the inclined track, the lower truck of the flat car may be adjusted in such a manner as to permit changing the angle of the platform with reference to the track. The car on which the pumping unit is mounted is shifted up and down the inclined track, depending upon the stage of the river, by means of a 3/8-inch flexible wire cable connected to the winding drum of a hand winch located at the top of the river bank.

Force main —Connecting the intake pipe with the plant is the river-water force main, consisting of a 4-inch screw-joint steel pipe about 1,200 feet long, laid at a minimum depth of 4 feet This part of the construction work was beset with difficulties, owing to the necessity of laying the pipe under two paved streets having a very heavy traffic and under the main tracks of the Pennsylvania Railroad (See fig 2.)

Sewage and dilution water —As previously noted, provision is made for continuous supplies of sewage, and likewise of filtered water for dilution purposes, thus making it possible, by mixing either one or both of these supplies with the river water, to obtain a raw water ranging from sewage to a highly diluted river water Domestic sewage from a residential section of the city is obtained from a near-by intercepting sewer by gravity flow through a 1½-inch pipe to the basement of the plant, where it is either pumped directly to the mixing device or allowed to flow into an equalizing tank, from which it is pumped to the mixing device. The sewage-equalizing tank has a capacity of 1,200 gallons, providing approximately 18 hours of detention for the raw sewage when drawn through the tank at a rate sufficient to provide an admixture of 1 per cent with the river water A single-stage centrifugal pump, with a 1½-inch suction and a 1-inch discharge, is used for pumping the raw sewage. This unit has a capacity of 25 gallons per minute against a working head of 40 feet A flushing connection is located so that either the sewage influent pipe from the intercepting sewer to the pump or the section extending through the pump and to the mixing device may be flushed separately. The dilution water is pumped directly from the filtered-water reservoirs to the mixing device

Mixing device —For mixing the various raw-water components, a device of the hydraulic-jump type is used. The hydraulic-jump mixing flume, invented by Mr. J. W. Ellms, was designed by him for this plant. The receiving tank is divided into three compartments, one of which receives river water, another sewage or dilution

water, or both together, and a central compartment into which the various components of the raw water are measured by means of 90° V-notched weirs Hook gauges are used to measure the flow of the river water, sewage, and dilution water. From the middle compartment the water flows to the inclined flume, which has a drop of 3 feet in a length of 10 feet, and in which the water attains a velocity of approximately 9 feet per second at the bottom. A submerged weir, set in the horizontal portion of the flume, builds up a standing wave, in which the components forming the river water become mixed. From the lower tank of the mixer the water flows by gravity to the coagulation basin.

Coagulation basin.—The coagulation basin is 37 feet long, 16 feet wide, and 11 feet 6 inches deep, inside dimensions. The basin proper is constructed of reinforced concrete, with a wooden longitudinal baffle extending through the middle of the tank and wooden stilling boxes at each end. The longitudinal baffle extends to within 9 feet 8 inches of the far end of the basin, leaving a clear space, 8 feet wide, between the end of the baffle and the stilling box for flow around the end of the baffle. Provision is made for closing this 8-foot space by means of stop planks, thereby dividing the basin into two separate compartments. The normal capacity of the basin is 45,000 gallons, providing a nominal detention period of slightly more than six hours. When the plant is operated at half its nominal capacity—that is, when only one filter unit is in service—the stop planks are put in position and one-half of the coagulation basin is used, or, if desired, the entire basin may be used with one filter unit, giving a nominal detention period of approximately 12 hours. Influent and effluent connections are arranged so that the two compartments into which the basin is divided may be operated either in series or in parallel. With these several combinations of tank and filter units, periods of sedimentation equal to 3, 6, or 12 hours, respectively, are available.

Filters—There are two rapid sand filter units of reinforced concrete construction, each one providing a net filtering area equal to 4 by 7 feet, or 28 square feet. The normal rate of filtration is 2 gallons per square foot per minute The filter sand is washed Ohio River sand, 27 inches deep, with effective size 0.42 millimeter and a uniformity coefficient of 1.50 Underlying the sand bed is a gravel layer 14 inches deep and graded in size from 1¼ inches at the bottom to less than ¼ inch at the top. A perforated pipe underdrain system is used, with 4½-inch diameter manifold and 1½-inch diameter laterals. The manifold is laid across the center of the filter, parallel to the smaller dimension, with eight laterals on each side, spaced at 6 inches on centers. The laterals are drilled with $\frac{9}{32}$-inch holes, staggered every 6 inches along the under side of the laterals in two

lines at 45° with the vertical. Semicircular wash-water gutters are placed to permit high-velocity washing up to an equivalent of 25 inches vertical rise per minute. A normal wash rate of 16 inches vertical rise per minute is used Simplex rate controllers, capable of being adjusted to carry rates of flow varying from 50 to 120 gallons per minute, are provided on each one of the filter effluent lines. Direct-reading glass-tube gauges are used for registering the loss of head, one tube being connected to a pipe through the filter wall just above the sand layer and the other to the filter-effluent line just ahead of the rate controllers.

Clear-water reservoirs—There are two separate clear wells, one under each filter Each clear well is 5 feet deep, providing a detention period of about 20 minutes at normal rates of operation. Connections between the filters and the clear wells permit the effluent from either one or both of the filters to be discharged into either clear well A separate overflow for each clear well connects with a single effluent pipe provided with an integrating water meter of the "detector" type for registering the total amount of water flowing from the filters The effluent line discharges into a "sump" overflowing into a near-by sewer

Chlorinator.—Chlorine is applied usually to the filtered water at its entrance to the clear wells by means of a small Wallace & Tiernan chlorinator of the manually controlled, solution feed type. Provision also is made for adding chlorine to the coagulated and settled water immediately prior to its filtration, and likewise for chlorination of the raw water just before its entrance into the sedimentation basin In the latter instance it is necessary to use an auxiliary injector in order to force the chlorine solution into the raw-water pipe against the added pressure of water at the basin level.

Wash-water storage.—For storing water for washing the filters, an elevated wooden tank is provided, 10 feet in diameter and 8 feet 6 inches deep, with a storage capacity equal to 4,800 gallons. Wash water is pumped to this tank from the filtered-water reservoirs by means of a single-stage centrifugal pump, having a 2-inch suction and a 1½-inch discharge, direct connected to a three-horsepower induction motor. This pumping unit has a capacity of 60 gallons per minute against a head of 45 feet. The wash-water pump also is used for pumping dilution water from the clear wells to the hydraulic-jump mixer.

Coagulant system.—The coagulant feed system comprises the ordinary type of solution feed apparatus, providing for the addition of alum, iron sulphate, and lime, either separately or in conjunction with each other. Three small wooden tanks, each 3 feet in diameter and 4 feet deep, of 200 gallons capacity, are used for preparing and storing the solutions of coagulating chemicals. The lime tank is

equipped with a mechanical agitator, consisting of a vertical rotating shaft carrying two paddle vanes inclined at an angle of 30° with the horizontal, and connected by a belt to a ⅛-horsepower electric motor.

Three cast-iron porcelain-lined orifice boxes are used for measuring the chemical solutions. The orifice boxes are provided with float-regulated inlet valves, adjusted to maintain a constant level of solution in the box for any given rate of flow Each box also is equipped with an adjustable slotted orifice, with tight-jointed sliding cover plate actuated by an adjusting spindle and graduated head All bends in the chemical piping are made of "tees" with their open ends screw plugged, and provision is made for a flushing-water connection on each one of the distributing lines. The chemicals are usually applied to the raw water just at the end of the flume in the lower tank of the hydraulic-jump mixer. Additional chemical distribution lines are provided, permitting the addition of coagulant solution to the water at the mid-point of its travel through the coagulation basin, and also as the water leaves the coagulation basin just prior to its application to the filters.

Piping—All piping throughout the plant is 4 inches in diameter, with the following exceptions: (*a*) Wash-water delivery main, wash-water drain, and clear-well overflows, which are 6 inches in diameter; (*b*) wash-water suction pipe, 2 inches; (*c*) chemical drain pipes, and sewage-equalizing tank influent, effluent, and drain pipes, 1½ inches; (*d*) chemical distribution piping, 1 inch; and (*e*) flushing-water lines, ¾ inch.

Operation schedule.—The plant is operated usually during 24 hours each day and 6 days every week. Three attendants are employed, working in three shifts of eight hours each. Complete operation records are kept, gauges and meters being read hourly A monthly summary of daily operations and laboratory results is prepared, giving, in addition to the data taken directly from the operating and laboratory records, certain special information bearing on the interpretation of the data secured from the various experiments. Any unusual or abnormal occurrences are fully recorded in a diary, in which also is maintained a detailed description of the experiments.

Sample collections.—The routine collection of water samples is carried out on a more extensive scale than is customary at a majority of full-scale plants, the total number of samples examined daily ranging from 20 to 36. In each routine collection, of which from 4 to 6 are made daily, samples are taken of the river water, of sewage, if it is being used, of the raw water, of the applied water, of the filtered water, and of the chlorinated water. The samples of filtered and chlorinated water are taken from sample cocks located in the

respective effluent lines, and the other samples are taken by dipping the sample bottle into the water to be sampled.

Laboratory control—The laboratory examinations are mainly bacteriological, but routine tests are made of turbidity, alkalinity, and the pH of the various samples. Bacteriological examinations include the 37° C agar count, and the usual quantitative tests for the presence of members of the *B. coli* group For the determination of the *B. coli* index in the filtered and disinfected water, 5 standard portions of 10 cubic centimeters each are inoculated from each sample, in accordance with the procedure recommended in testing conformant to the Treasury Department standard Additional single portions of 1 cubic centimeter and 0 1 cubic centimeter of samples from these two sources are likewise tested for *B coli*

At the present writing the experimental plant has been operated on a regular schedule for 20 months, of which time 15 months have been devoted primarily to a study of the efficiencies of bacterial removal obtainable under varying conditions with respect to raw-water pollution At the present time increased attention is being given, and in the immediate future will be given, to problems of a special nature closely allied with the main objectives of these studies.

In planning and carrying out the experimental studies, the constant advice and assistance of Mr. Joseph W. Ellms, of Cleveland, Ohio, who has served as a special consultant for this work, have been most generously given to the personnel having these studies in hand. Mr. Ellms's aid, based on his long experience, both in the practical management of water-purification plants and in extensive research work concerned with their operation, has been a valuable asset in this connection.

II. PRELIMINARY REVIEW OF RESULTS OF PRIMARY EXPERIMENTS

By H W STREETER, Sanitary Engineer, United States Public Health Service

In the preceding article of this series a description has been given of an experimental water-purification plant which has been constructed and is now being operated by the United States Public Health Service on the grounds of the laboratory of stream pollution investigations at Cincinnati, Ohio. In the present article it is proposed to give a preliminary review of the experimental work thus far undertaken at this plant and to discuss briefly some of the more outstanding results of that part of the experiments which has been concerned more especially with the primary objective of these studies.

The primary objective in question, as stated by Mr. Moss, was "that of providing a means whereby a detailed study could be made of the limits of raw-water pollution which are consistent with the production of effluents conforming to accepted standards of bacterial quality, having reference to water-purification plants of the type

found along the Ohio River and on other similar river systems of the country serving as sources of purified municipal water supplies." It also has been noted in the paper by Mr. Moss that, prior to the construction of the experimental plant, two series of observations bearing on this question had been made at selected groups of municipal water-purification plants located in various parts of the Eastern and Middle Western States. The results of these observations having indicated a need for a further study of the problem under conditions subject to experimental control, the experimental plant was constructed chiefly with this end in view, though it also was intended for a secondary purpose, which may be described briefly as follows:

The secondary objective in question, for which the experimental plant is well adapted, has been an evaluation of the different factors, subject to the control of the plant operator, which influence, directly or indirectly, the cost and bacterial efficiency of water purification. The purpose of these observations is to provide a basis for judgment as to the possibilities which may exist for securing, at a reasonable cost, an increased efficiency of bacterial removal by plants in current service without entailing any radical changes in their design or construction. On this question hinges that of whether it may be necessary ultimately to revise any permissible limits of raw-water pollution which may be established from observations made under present conditions of plant operation, on which the portion of this study concerned with the primary objective above stated has been based. These secondary experiments having been in progress but a short time at the present writing, no discussion of their results is justified in this paper, which, as previously noted, is concerned wholly with the experiments having reference to the primary objective of the studies.

In conducting these primary experiments it was desired to reproduce, as nearly as practicable, conditions of operation of the plant such as are found at the average full-scale municipal plant in routine service. With this end in view, the experimental plant has been operated throughout the entire 24 hours of each working day, as noted in the paper by Mr. Moss, and care has been taken to follow normal operating practice closely in every detail, likewise, to produce an effluent comparable, both physically and chemically, with effluents as ordinarily delivered by municipal plants along the Ohio River and other rivers of similar type.

In view of the fact that it is necessary to discontinue operation of the plant every Sunday, it has been convenient to regard the six working days of each week as the unit of time for the experiments, which have been divided, accordingly, into a series of weekly "runs," each one of which has constituted virtually an individual experiment.

The procedure followed in making the individual experiments, though governed to some extent by circumstances, has been aimed, in general, to facilitate, as far as practicable, a direct observation of the relations existing between the bacterial quality of the raw water and the resulting quality of the effluents produced at successive stages of treatment. This relationship, it will be noted, provides the basis for determining the limiting densities of raw-water bacteria which are consistent with producing effluents of specified bacterial quality.

Theoretically, an ideal procedure would consist in starting a given experiment with a raw water polluted bacterially to a relatively slight degree, such that the quality of the effluent produced from it were better by a considerable margin than the limit fixed by the assumed standard. From this initial condition the bacterial content of the raw water would be increased gradually until the quality of the effluent became deteriorated decidedly below the standard, noting the corresponding changes occurring progressively in the quality of raw water and effluent throughout the period of the observations If a definite relationship existed between the density of bacteria in the raw water and in the effluent, the raw-water condition at which overburden occurred would be indicated by the abscissa of a point on the relationship curve the ordinate of which exactly equaled the limiting bacterial content of the effluent as fixed by the particular standard assumed.

In following the procedure described it originally was intended to increase the bacterial content of the raw water at intervals of every few hours, holding it constant during these periods and noting the effect produced on the quality of the effluent in consequence of each successive raw-water change, making due allowance for the time of passage of water through the plant. This procedure, however, was found to be subject to numerous difficulties, owing chiefly to sudden and unexpected changes occurring in the bacterial content of the river water during the periods in which it was desired to hold it constant [1] The method finally adopted in a majority of the experiments was similar to the one above described, except that the character of the raw water was adjusted at intervals usually of one or two days and the results of the observations averaged by days, rather than considered individually. In this manner it has been possible to minimize unbalanced errors in the observations due to uncontrollable variations in the character of the raw water occurring during a given day.

---

[1] The only reasonable explanation assignable as to the cause of these sharp changes is afforded by the fact that considerable volumes of sewage are discharged into the river at several points located along the Cincinnati shore and not far upstream from the intake. The sewage from these sources is known to undergo hourly changes, sometimes erratic in character, both in its flow and in its composition It is entirely probable that these variations are frequently communicated directly to the river water at the intake

In order to cover a sufficiently wide range of raw-water bacterial content, it has been necessary to repeat the individual experiments several times under each condition of season and raw-water turbidity encountered during the period of the observations, the experiments made under each condition having been planned, as far as practicable, to cover a series of different but slightly overlapping ranges of bacterial densities It was expected originally that the required range of variation in this respect could be secured by adding sewage to the river water whenever necessary to augment the normal fluctuations in the composition of the latter. Owing, however, to the high degree of pollution of the river water at the plant intake by sewage discharged into the river at points immediately upstream, it was found necessary frequently to dilute the river water with filtered water from the municipal supply in order to reduce its bacterial density sufficiently to bring it within the desired range.

RESULTS OF PRIMARY EXPERIMENTS

The results of the primary experiments may be considered advantageously from the following standpoints. (*a*) The crude relationships indicated as existing between the bacterial quality of the raw water and the corresponding quality of the effluents produced at successive stages of treatment; (*b*) the manner and extent to which this relationship is shown to be affected by variations in certain factors, notably by variations in raw-water turbidity and in temperature and other seasonal conditions; (*c*) the extent to which the efficiency of bacterial purification shown by the experimental plant has been found to agree with the corresponding efficiency of full-scale municipal plants of the same type under similar conditions of raw-water pollution; and (*d*) the indicated limits of bacterial pollution of the raw water consistent with the production of effluents conforming to given standards of bacterial quality Each one of these four points will be discussed separately and in the order above given.

RELATIONS BETWEEN BACTERIAL QUALITY OF RAW WATER AND CORRESPONDING QUALITY OF EFFLUENTS

For the purpose of combining the results of the observations in such a manner as to show the average relations existing between the degree of bacterial pollution of the raw water and the corresponding bacterial quality of the effluents produced at various stages of treatment, the statistical method found to be most suitable was the same one which previously had been followed in analyzing a more extensive series of data obtained from the two collective studies of municipal plants to which reference has been made. This method, which has been described in a previous article,[2] has consisted in grouping the

[2] Reprint No. 737 from the Public Health Reports, Mar 31, 1922, p 4.

data according to the numbers of bacteria observed in the raw water and averaging, for each group, the numbers observed coincidently in the raw water and in the effluent from each successive stage of treatment The results obtained from thus grouping and averaging the daily means, expressed both in terms of the bacteria growing at 37° C and of members of the *B coli* group in terms of the usual *B coli* index, are given in Table 1, in which are also given the corresponding residual percentages of plate growers and of *B. coli*, referred both to the raw water and to the influent water of each stage.

TABLE 1 —*Relations between numbers of bacteria observed in the raw water and corresponding numbers observed at successive stages of treatment, as obtained by grouping the results according to numbers of raw-water bacteria falling within specified ranges*

[1] No results available

A mere inspection of Table 1 is sufficient to indicate the existence of a decided correlation between the density of bacteria of both classes, as observed in the raw water and the corresponding densities in the effluent from each successive stage of treatment. In Figure 1, in which the *B. coli* data given in Table 1 have been plotted on logarithmic scales (the raw-water counts being plotted as abscissæ and the corresponding effluent counts as ordinates), the relationship is shown to approach very closely the form of a power function, which may be represented by the simple equation: $E=cR^n$, in which R denotes the bacterial content of the raw water, E the corresponding content of the effluent, and c and n empirical constants, the value of which has been found to vary with the type of purifi-

cation process, the class or kind of bacteria, and the number of intermediate stages of treatment between the source of raw (or influent) water and the particular effluent considered. Though not here given, a similar plot of the 37° C. plate count figures in Table 1 can readily be shown to follow the same trend as that of the *B. coli* data.

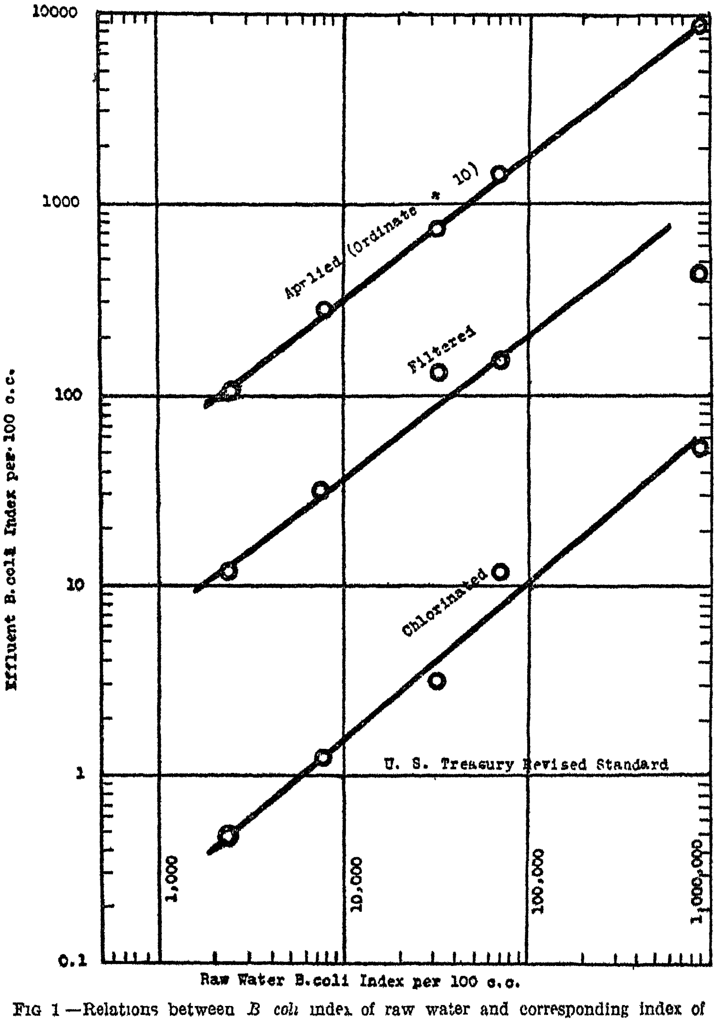

FIG 1.—Relations between *B coli* index of raw water and corresponding index of effluents from successive stage of treatment (Plot of data given in Table 1)

The values of *c* and *n*, as derived from plots of the data such as are given in Table 1, may be tabulated as follows:

	24-hour count, 37° C.		*B. coli* index	
	c	*n*	*c*	*n*
Applied water	11.0	0 55	0.34	0.75
Filtered water	.32	.61	.029	.77
Chlorinated water	.0011	.91	.0008	.82

From a study of these data the following indications of interest may be noted:

1. That the correlation observed between the *B. coli* index of the raw water and that of the various effluents is slightly smoother than the corresponding correlation as observed between the numbers of bacteria growing on agar plates at 37° C.

2. That the values of *c*, as derived from the *B coli* relationships, are of a lower order of magnitude than those derived from the corresponding plate-count data.

3 That the values of *n* derived from the two series of plots are of a similar order of magnitude, but differ in that they are more uniform in their values as derived from the *B coli* data.

4 That the residual percentages of plate growers and of *B coli*, as referred to the raw water, show a tendency toward a progressive diminution with increasing raw-water content, but that this trend is due largely to the effect of coagulation and sedimentation, as is evidenced by the fact that the residual percentages in the unchlorinated and chlorinated filter effluents when referred, in each instance, to the influent water of the immediately preceding stage, do not show a similar trend.

In addition, it may be noted that a rather decided tendency is shown toward decreasing efficiency of *B. coli* removal by chlorination coincidently with increasing densities of *B coli*, both in the raw water and in the unchlorinated filter effluent. Whether or not this tendency is due to the presence of larger amounts of organic matter in the filter effluent coinciding with higher numbers of bacteria is a question requiring further study. The efficiency of filtration with respect to the removal of both classes of bacteria enumerated is shown to remain practically constant, irrespective of the numbers present either in the raw water or the filter influent water.

INFLUENCE OF CHANGES IN SEASON AND VARIATIONS IN RAW-WATER TURBIDITY ON FOREGOING RELATIONSHIPS

The influence exerted by seasonal changes and variations in raw-water turbidity on the foregoing relationships may best be gauged by analyzing the results of the observations covering 12 consecutive months, comprising a complete seasonal cycle. For the 12 months extending from October 1, 1924, to September 30, 1925, inclusive, covering the first full year of routine operation of the plant, the effect of changes in season on these relationships may be considered according to three periods: (*a*) December to March, inclusive, representing winter conditions; (*b*) June to September, inclusive, representing summer conditions; and (*c*) the remaining four months of the year, representing intermediate seasonal conditions. These periods have been selected arbitrarily, chiefly for convenience in separating the

data, and it is realized that they afford only a rough basis for a seasonal classification of the material at hand.

In analyzing the data from the standpoint named the conclusions to be derived from such an analysis may be clarified by noting that a simple index of the effect of a given factor, such as change in season, on the relations existing between the bacterial content of the raw water and that of a particular effluent is afforded by comparing the residual percentages of bacteria observed in the effluent for each separate condition assumed (in this case the three seasonal periods), when the average turbidity and bacterial content of the raw water are of about the same magnitude in each instance. Thus, if the residual percentages of bacteria observed during the three seasonal periods named were approximately the same, when the average turbidity and the bacterial content of the raw water were of similar magnitude in each one of the three periods, it would be concluded that the relation existing between the bacterial content of the raw water and that of the effluent were relatively unaffected by seasonal changes. This is true for the reason that any change in the relationship between the two given variables, if one of them remain constant, is necessarily reflected by a corresponding change in the ratio existing between them

For the purpose at hand the proper method of classifying the data statistically would consist in making, for each seasonal period, a primary separation of the material according to raw-water turbidity, and, secondarily, a classification of the material in each turbidity group according to raw-water bacterial content, the method of separation in each instance being similar to that which has been described in explaining the derivation of Table 1. This procedure would thus provide a basis for comparing the residual percentages of bacteria observed in the three seasonal periods under approximately the same conditions with respect to raw-water turbidity and bacterial content.

In the present instance, however, no effort will be made to show the results obtained except as derived from a simple classification of the material, first, according to season, and, second, according to raw-water bacterial content, which classification appears to have brought out the essential points fully as well, for all practical purposes, as the more elaborate one above described. The results obtained from the first step of the classification are given in Table 2 and, from the second step, in Table 3. From these two tables the following broad conclusions may be drawn:

1. That the over-all efficiency of bacterial removal, including chlorination, as regards both the plate growers and the *B. coli*, appears to be relatively little affected by seasonal changes, this being especially true of the *B. coli*.

TABLE 2.—*Comparative average numbers of bacteria and corresponding numbers and residual percentages of bacteria observed, respectively, in the raw water and in the effluents from successive stages of treatment during three different seasonal periods of four months each, during the year October, 1924, to September, 1925, inclusive*

BACTERIAL COUNT 24 HOURS, 37° C

Chlorinated	11 5	9 2	2 3

2 That the bacterial efficiency of separate stages of treatment is influenced to a measurable extent by seasonal changes, that of filtration apparently being higher in winter than in summer and that of chlorination vice versa The *B coli*, however, appear to be less affected in this respect than do the bacteria growing on plates at 37° C.

The second point to be considered in this connection is the effect, if any, exerted on the efficiency of bacterial removal by variations in raw-water turbidity. The method of analyzing and presenting the data from this standpoint has been the same as that followed in studying the effect of seasonal changes, except that the primary classification of the material, instead of being made according to three seasonal periods, has been made according to raw-water turbidities falling within the three arbitrary groups 0 to 10, 11 to 100, and over 100, representing, respectively, a relatively clear, a moderately turbid, and a decidedly turbid raw water. In this, as in the preceding instance, a simple classification of the material, first, according to raw-water turbidity, and, second, according to raw-water

bacterial content, appears to have brought out all of the essential points concerning the influence on bacterial efficiency exerted by variations in raw-water turbidity.

TABLE 3.—*Comparative average numbers of bacteria and corresponding numbers and residual percentages of bacteria observed, respectively, in the raw water and in the effluents from successive stages of treatment during the same three seasonal periods as indicated in Table 2 and coinciding with raw-water numbers falling within specified ranges*

1. That the over-all efficiency of removal of bacteria growing on agar plates at 37° C. is influenced decidedly by variations in raw-water turbidity, chiefly, however, because of the effect of this factor on the bacterial efficiency of preliminary coagulation-sedimentation.

2 That the over-all efficiency of *B. coli* removal is influenced in no orderly manner and to a very slight, if any, extent by variations in raw-water turbidity.

3. That the only separate stage of treatment the bacterial efficiency of which appears to be affected in any consistent manner by variations in raw-water turbidity, is that of preliminary coagulation-sedimentation, which becomes higher with increased turbidity. This statement does not apply, however, to the efficiency of *B coli* removal, which does not appear to be influenced in any consistent direction or to any material extent at any stage of treatment by variations in raw-water turbidity.

Perhaps the most significant general conclusion to be derived from the foregoing data is that the efficiency of *B. coli* removal, whether considered in reference to the purification process as a whole or to any given stage of it, has not been evidenced as being influenced consistently or measurably either by changes in season or by variations in raw-water turbidity. This finding, which confirms that of the previous collective study of a group of full-scale municipal plants, is of basic importance, owing to the sanitary significance of the *B. coli* group of bacteria and to the indication which it gives that the

relations existing between the *B. coli* content of the raw water and that of the effluents from various stages of treatment is virtually unaffected by either of the two factors considered. In view of this indication, the *B coli* relationship shown in Table 1 and illustrated in Figure 1 may be regarded as being of basic significance, in so far as the results of this study are concerned

COMPARABILITY OF EXPERIMENTAL RESULTS WITH THOSE OF FULL-SCALE PLANTS OF SIMILAR TYPE

The extent to which the efficiency of bacterial purification shown by the experimental plant has been found to agree with the corresponding efficiency of full-scale municipal plants of the same type under similar conditions of raw-water pollution is a question of basic importance in the current studies, as the applicability of conclusions derived from the experimental studies to conditions of full-scale operation depends, to a large extent, on the degree of accordance existing between the performance of the experimental plant from this standpoint, as compared with that of full-scale plants under the same conditions.

In order to make a proper comparison in this respect, it has been desirable, for obvious reasons, to select for the purpose, laboratory data only from full-scale plants at which the conditions as regards the type and elaboration of treatment, the character and density of pollution of the raw water treated, and the physical operation of the plant closely parallel those existing at the experimental plant It is desirable, moreover, to consider in this connection only plants supplying laboratory data fairly comparable with those obtained from the experimental plant.

For the purpose at hand the most suitable data for comparison with those of the experimental plants are the results obtained from observations made at 10 municipal filtration plants located on the Ohio River, in connection with the collective survey to which reference has been made. Five of these ten plants have single-stage coagulation and sedimentation, which was the kind of preliminary treatment used in the experiments discussed in this paper. In Table 6 are given, in parallel columns, the averages of the yearly mean 37° C. bacterial counts and *B. coli* indices observed in the raw waters and effluents of these five plants, together with corresponding averages of the experimental results obtained during periods in which the bacterial content of the raw water fell within the range of magnitude coinciding most nearly with the average range of the five raw waters in question.[3] In the right-hand section of the table are given the

[3] The range in question included all *B coli* results observed in the raw water and the corresponding results observed in the various effluents for days on which the mean raw-water *B coli* index was equal to or less than 10,000 per 100 cubic centimeters.

corresponding residual percentages of plate-growing bacteria and of *B. coli*, referred both to the raw water and to the influent water of each separate stage.

TABLE 6.—*Averages of numbers of bacteria and of B. coli in raw waters and effluents of five Ohio River filtration plants having single-stage coagulation and sedimentation, as compared with corresponding averages of numbers observed at experimental plant in most nearly coincident ranges of raw-water numbers*

	Average content		Residual per cent of raw-water content	
	Ohio River plants	Experimental plant	Ohio River plants	Experimental plant
24-hour count, 37° C. (per cubic centimeter)				
Raw	3,460.0	3,880.0	----------	----------
Applied	601.0	1,050.0	17.4	27.1
Filtered	27.0	48.0	.8	1.2
Chlorinated	4.4	2.2	.12	.06
B. coli index (per 100 cubic centimeters)				
Raw	4,570.0	3,180.0	----------	----------
Applied	1,030.0	1,270.0	22.5	39.9
Filtered [1]	3.5	3.9	.08	.12
Chlorinated [1]	.6	.5	.013	.016

[1] Based, in both instances, on results obtained from tests of five 10 cubic centimeter portions of all samples.

In order to make a proper comparison of the two series of *B. coli* data, it has been necessary to reduce the experimental results obtained from tests of the unchlorinated and chlorinated effluents to a basis of those derived from tests only of five 10 cubic centimeter portions of each sample, owing to the fact that this method was followed at the five Ohio River plants during the year covered by the averages. This procedure involved recalculating, in the experimental series, the *B. coli* index for each individual sample, after eliminating all results of tests of 1 cubic centimeter and 0.1 cubic centimeter portions, and reaveraging, on this basis, the results falling within the raw-water range above stated.

The figures summarized in Table 6 indicate a very fair degree of correspondence between the two series of observations, making due allowance for individual divergences to be expected in them. The only well-marked divergence between the two series appears to be in the residual percentages of both classes of bacteria observed in the water applied to the filters, which represents the product of preliminary coagulation and sedimentation. In this single instance the efficiency of bacterial removal is indicated as having averaged distinctly higher at the five Ohio River plants than as observed at the experimental plant, which difference is explainable, at least in part, by the fact that the arrangements provided for preliminary mixing of the coagulant solutions with the raw water are somewhat less highly elaborated at the experimental plant than at the five Ohio River plants. This divergence, however, is virtually offset by

the greater bacterial efficiency of the filtration stage at the experimental plant, which is sufficient to deliver an over-all efficiency up to and including the unchlorinated filter effluent averaging but 0.4 per cent less than that of the five Ohio River plants as based on the removal of 37° C. plate-growing bacteria, and but 0.04 per cent less as based on the removal of *B. coli*. As far as both the unchlorinated and chlorinated filter effluents are concerned, the residual percentages given in Table 6 indicate no significant differences as existing between the bacterial efficiency of the experimental plant and that of the five Ohio River plants, considered as a group.

To summarize broadly the foregoing observations, they may be regarded as indicating that the over-all bacterial efficiency of the experimental plant, both with and without the aid of chlorination, agrees very closely with the corresponding average efficiency of the five Ohio River municipal plants having the same degree of elaboration as regards the treatment given the water and under similar conditions of raw-water pollution Inasmuch as the five Ohio River plants in question may be taken as fairly representing the average plant of the same type treating water similar to that of the Ohio River, the results obtained from the experimental plant in the respect named should be capable of application to normal conditions of full-scale operation without any substantial modification.

INDICATED LIMITS OF RAW-WATER POLLUTION CONSISTENT WITH PRODUCING EFFLUENTS CONFORMING TO GIVEN STANDARDS OF BACTERIAL QUALITY

On referring to Figure 1 it will be noted that the abscissa of each plot corresponding to a given ordinate defines the average *B. coli* index of the raw water consistent with producing an effluent having a specified *B coli* index. Similarly, a plot of the 37° C. plate-count data given in Table 1 would show the limiting bacterial pollution of the raw water, expressed in these terms, which was found to be consistent with producing an effluent having any assumed bacterial content, as expressed in the same terms. An alternative method of determining these limiting raw-water values would consist in substituting into the general equation, $E=cR^n$, values of c and n as given on page 2134 and calculating, for an assumed value of E, the corresponding raw-water content, R.

In this connection it is of particular interest to determine the limiting average *B. coli* index of the raw water which is indicated as being consistent with producing unchlorinated and chlorinated filter effluents, respectively, conforming to the revised United States Treasury Department *B. coli* standard. By transposing the equation above given it may be written thus: $R=\left(\frac{E}{c}\right)^{\frac{1}{n}}$. Referring to page 2134, the

values of c and n given for the relationship between the *B. coli* index of the raw water and that of the unchlorinated filter effluent are 0.029 and 0.77, respectively. The value of E, as defined by the revised United States Treasury Department standard and expressed in terms of the *B. coli* index, is 1 per 100 cubic centimeters. Substituting these values into the transposed equation, we have

$$R=\left(\frac{1}{0.029}\right)^{\frac{1}{0.77}}=(34.5)^{1.30}=100 \text{ per } 100 \text{ c. c.}$$

Similarly, the value of R consistent with producing a chlorinated effluent conforming to the same standard may be computed thus, taking as c and n the values given on page 2134:

$$R=\left(\frac{1}{0.0008}\right)^{\frac{1}{0.82}}=(1{,}250)^{1.22}=6{,}000 \text{ per } 100 \text{ c. c.}$$

On referring to the plots given in Figure 1, these computed values are approximately confirmed, the former by extrapolating the graph until its ordinate becomes equal to the value 1, representing the revised Treasury Department standard limit.

For comparison with these results, there are available two corresponding raw-water maxima derived from the analysis of an extensive series of data secured from the collective survey of the group of municipal plants which previously has been noted in this paper. From an analysis of these data, made in accordance with the same procedure as has been described, the maximum *B. coli* index of the raw water consistent with producing unchlorinated effluents conforming to the revised Treasury Department standard was indicated as being 60 per 100 cubic centimeters, and the maximum index consistent with producing chlorinated effluents meeting the same standard, 5,000 per 100 cubic centimeters. Making due allowance for observational errors and the "spread" of statistical data of this kind, the agreement between the two series of results is strikingly close. From these results it may be concluded tentatively that the limiting figures above stated are fairly representative of the maximum densities of raw-water *B. coli* which will permit the delivery, by efficiently operated plants treating Ohio River water, of unchlorinated and chlorinated effluents meeting the standard in question. It should be noted in this connection that these criteria refer to averages taken over periods of considerable length, such as a month or a year. It also should be emphasized that the raw-water maxima stated are merely observational ones and are not intended as working standards of raw-water pollution, which, if ultimately developed and applied, must necessarily provide proper factors of safety to take account of short-time fluctuations, both in the degrees of pollution

of different classes of raw waters and in the efficiency of bacterial removal effected by various types of purification processes Data bearing on this question, which have been collected from the surveys of municipal plants and from the current experimental studies, will be presented and discussed in a later paper of this series.

SUMMARY AND CONCLUSIONS

The primary series of experiments in water purification described in this paper have been designed to test experimentally the maximum degrees of raw-water bacterial pollution which are consistent with the production of effluents conforming to given standards of bacterial quality. These experiments, which were carried on over a continuous period of 15 months, embraced all conditions with respect to temperature, season, and character of raw water which are normally encountered in the treatment of Ohio River water and other waters of similar type The experimental plant, which has been described in the first article of this series, was arranged so as to permit the bacterial content and, to some extent, the physical character of the raw water to be varied at will over a wide range The general method of procedure in conducting the experiments consisted in varying over different ranges the bacterial and physical character of the raw water and observing the resultant effects produced on the quality of the effluents as delivered through successive stages of treatment

The results of these observations, only the more outstanding features of which are presented in this paper, have indicated—

1. That a consistent, orderly relationship exists between the bacterial quality of the raw water and that of the effluents produced from it at successive stages of treatment.

2. That this relationship is a simple power function, which can be expressed by the general equation, $E=cR^n$.

3. That the value of c and, to a considerably less extent, of n depends on the kind of bacteria, on the type of process, and on the number of stages of treatment between the source of raw water and that of the particular effluent considered.

4 That the efficiency of *B. coli* removal, and hence the relationship above described, when expressed in these terms, is virtually unaffected by seasonal changes or by variations in raw-water turbidity and is influenced by the density of *B. coli* only at the preliminary stage of coagulation-sedimentation.

5. That the results of observations obtained from the experimental plant may be applied without substantial modification to full-scale municipal plants of the same type and degree of elaboration and treating raw waters of approximately the same physical character and bacterial density.

6. That the indicated maximum limits of raw-water *B. coli*, consistent with producing unchlorinated and chlorinated effluents con-

forming to the revised United States Treasury Department standard, are 100 and 6,000 *B. coli* per 100 cubic centimeter, respectively, as expressed in terms of the *B. coli* index.

7. That these indicated maxima agree closely with corresponding maxima derived from previous collective studies of full-scale municipal plants, of the same type and treating raw waters of the same character, under conditions of their routine operation.

A general conclusion reached thus far from the experimental study has been that its results have confirmed, in every major respect, those of the observations made at full-scale municipal plants under the parallel conditions above stated. In the series of experiments in progress at this writing it is planned to devote further study both to the secondary objective which has been described in this paper and to determining, as far as is possible with the facilities at hand, the effects which are produced on the foregoing relationships by fairly wide differences in the physical character of the raw water. The results thus far secured from the observations made of certain of these effects appear to indicate, as far as is shown in Table 5, that the efficiencies of bacterial purification attained in the treatment of relatively clear raw water are not as widely divergent from those shown in the treatment of turbid water, all other things being equal, as had been anticipated prior to these experiments. Any conclusions drawn from these observations must be regarded, however, as being subject to qualification pending further studies of other factors which have a decided bearing on the problems to be met in the treatment of clear waters, as found along the Great Lakes and in various impounded sources of supply, in contrast with those which are involved in the purification of turbid river waters, such as exist in the inland streams of the United States. The facilities available at the present location of the experimental plant of the Public Health Service are hardly adequate for reproducing all of these factors; nevertheless, they may be utilized for the purpose of showing broadly the differences and the similarities existing between these two classes of water-purification problems. In subsequent papers of this series it is proposed to discuss more fully both the foregoing and other questions having a bearing on the final conclusions to be reached from these studies.

PUBLIC HEALTH ENGINEERING ABSTRACTS

Report of the Malaria Survey of the Jalpaiguri Duars.—Public Health Department of the Government of Bengal, Calcutta, 1926. (Abstract by L. D. Fricks.)

This report is published in pamphlet form and contains 67 pages. The object of the survey was to determine what improvement in the malaria situation had followed measures put into operation for

the control of mosquito production on the Meenglas Tea Estate, Jalpaiguri Duars, Bengal. Based on the assumption that the surest method of abolishing malaria in the long run is reduction or eradication of malaria-carrying mosquitoes, and because of the difficulty of controlling the human factor, coolie labor, extensive antimosquito measures were adopted at Meenglas. These measures consisted of underground drainage of streams, periodic flushing of streams, oiling of streams and pools, deepening, straightening and cleaning of streams. The topography of the locality surveyed is rolling, adjoining as it does the foothills of the Himalayas, and a rapid run-off of storm water takes place Excellent results were reported in taking care of residual water by means of underground or subsoil drains. The internal dimensions of the subsoil drains varied from 6 inches by 9 inches at the intake to 12 inches by 15 inches at the outlet. The drains were constructed of four sets of sized blocks of stone, one forming the base, two forming the sides, and the fourth the top of the drain, these being covered with dirt and turf. The gradient of these drains was 1 in 60 to 1 in 100, which was found sufficient to increase the velocity of water flow. The drains did not choke, except on rare occasions following the displacement of the top stone, and were found adequate to take care of drainage between floods. During heavy rains the storm water usually overflowed the drains. Antimosquito measures were first undertaken on the Meenglas estate in 1917. The system of subsoil drainage was completed in 1919. Oiling of surface water was added in 1919. The survey which is here reported was made in 1925. This survey comprised ten tea gardens or estates, in addition to the one on which antimosquito measures had been carried on for eight years.

The most important conclusions of the surveying party were as follows: (1) Antimosquito operations on the Meenglas Tea Estate had been entirely successful as shown by lower spleen rates observed; (2) unless antimosquito measures are undertaken over a comparatively large area in a highly malarious region, there may be no reduction in malaria because of the influx of mosquitoes from the outside, (3) subsoil drains once constructed require very little further attention; (4) oiling is cheaper than draining, but it requires greater attention to be made to work efficiently

The Disappearance of Malaria in a Village in France due to the Improvement of the Economic Condition of the Inhabitants. Et. Sergent, J. Chassaing and G Fabiani, *Arch. de L'Institut Past. d' Algerie*, Vol. 3, No. 2, 1925, pp. 127–131. (Abstract by M. A. Barber.)

Fifty years ago, Menet, a village of Haute-Auvergne, was malarious, but it is now healthful. The breeding of *Anopheles* there continues to be abundant, no mechanical protection against them has been

practiced, and there has been no change in the number of domestic animals for sixty years; no quinine treatment other than that which is general in France has been employed. The writers attribute the disappearance of malaria to improvement in the "well-being, the comfort, and the prosperity" of the people. They believe that these factors have been as effective in other parts of France, formerly malarious, as in the region described. They state that it is their conviction that one of the most powerful measures practicable in a malarious region is to amend the "Reservoir of virus" constituted by the inhabitants of the region

A List of the Fishes of Algeria Suitable for Use in the Destruction of Mosquito Larvæ. M. le Commandant Cauvet *Arch de L'Inst. Past d'Algerie*, Vol. 3, No. 2, 1925, pp. 146–154. (Abstract by M. A Barber)

A list with illustrations is given of the fishes of Algeria suitable for antimalaria work. The most effective species is *Phoxinellus chaignoni*, which is preferred for the following reasons: It is adaptable to a great variety of waters; it may withstand temperatures over 30° C; it reproduces rapidly, it feeds at all depths of water; and through its great activity, it is more capable than other fishes of escaping its enemies.

Menace of Cross Connections in a Public Water Supply. R. F. Goudey, Resident Engineer, State Board of Health, Los Angeles, Calif *Journal American Water Works Association*, Vol 15, No 5, May, 1926, pp 472–480. (Abstract by Sol Pincus.)

Another forceful discussion is presented of the serious consequences of cross connections in water supply practice. The author shows the great dangers that exist from the presence of such connections, even with check valves and gate valves, which he does not hold are safe and reliable protections. The numerous kinds and varieties of cross connections are referred to. Reference is also made to the many typhoid fever outbreaks attributed to cross connections.

The only remedy to be considered, according to the author, is the total discontinuance of every cross connection with a polluted supply. The author seems to indicate that the cities of Lowell and Philadelphia and the States of Washington and Minnesota are the only localities requiring complete separation of the two supplies; and that these two States with Ohio, Pennsylvania, and California are the only States having regulations controlling cross connections. He claims that the limited attention to this matter is due to the lack of appreciation of the importance of the dangers. (Abstractor's Note: The author's list is very incomplete. Action regulating cross connections has been taken by the cities of Hartford, Chicago, New York, and by the States of Connecticut, New York, Indiana, and Kansas, to cite some additional places.)

DEATHS DURING WEEK ENDED SEPTEMBER 18, 1926

Summary of information received by telegraph from industrial insurance companies for week ended September 18, 1926, and corresponding week of 1925 (From the Weekly Health Index, September 22, 1926, issued by the Bureau of the Census, Department of Commerce)

	Week ended Sept 18, 1926	Corresponding week 1925
Policies in force	65,301,677	61,025,105
Number of death claims	11,485	11,147
Death claims per 1,000 policies in force, annual rate	9.2	9.5

Deaths from all causes in certain large cities of the United States during the week ended September 18, 1926, infant mortality, annual death rate, and comparison with corresponding week of 1925 (From the Weekly Health Index, September 22, 1926, issued by the Bureau of the Census, Department of Commerce)

[1] Annual rate per 1,000 population
[2] Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
[3] Data for 63 cities
Deaths for week ended September 17, 1926
[5] In the cities for which deaths are shown by color, the colored population in 1920 constituted the following percentages of the total population Atlanta 31, Baltimore 15, Birmingham 39, Dallas 15, Fort Worth 14, Houston 25, Indianapolis 11, Louisville 17, Memphis 38, Nashville 30, New Orleans 26, Norfolk 38, Richmond 32, and Washington, D C, 25.

PREVALENCE OF DISEASE

No health depaitment, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

Diphtheria.—For the week ended September 11, 1926, 36 States reported 832 cases of diphtheria. For the week ended September 12, 1925, the same States reported 1,039 cases of this disease. Ninety-nine cities, situated in all parts of the country and having an aggregate population of nearly 30,000,000, reported 438 cases of diphtheria

for the week ended September 11, 1926 Last year for the corresponding week they reported 523 cases. The estimated expectancy for these cities was 613 cases The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Measles—Thirty-five States reported 635 cases of measles for the week ended September 11, 1926, and 290 cases of this disease for the week ended September 12, 1925. Ninety-nine cities reported 152 cases of measles for the week this year, and 126 cases last year.

Poliomyelitis—The health officers of 35 States reported 118 cases of poliomyelitis for the week ended September 11, 1926. The same States reported 255 cases for the week ended September 12, 1925.

Scarlet fever—Scarlet fever was reported for the week as follows: Thirty-six States—this year, 831 cases; last year, 801 cases; 99 cities—this year, 334 cases; last year, 290 cases, estimated expectancy, 302 cases

Smallpox.—For the week ended September 11, 1926, 36 States reported 147 cases of smallpox. Last year for the corresponding week they reported 81 cases. Ninety-nine cities reported smallpox for the week as follows: 1926, 11 cases, 1925, 31 cases, estimated expectancy, 20 cases. No deaths from smallpox were reported by these cities for the week this year.

Typhoid fever.—One thousand two hundred and thirty-four cases of typhoid fever were reported for the week ended September 11, 1926, by 36 States. For the corresponding week of 1925, the same States reported 1,231 cases of this disease. Ninety-nine cities reported 255 cases of typhoid fever for the week this year, and 230 cases for the corresponding week last year. The estimated expectancy for these cities was 241 cases.

Influenza and pneumonia.—Deaths from influenza and pneumonia were reported for the week by 93 cities, with a population of more than 29,200,000, as follows: 1926, 311 deaths; 1925, 361 deaths.

City reports for week ended September 11, 1926

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence how many cases of the disease under consideration may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Public Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding week of the preceding years. When the reports include several epidemics or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1917 is included. In obtaining the estimated expectancy, the figures are smoothed when necessary to avoid abrupt deviations from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

Division, State, and city	Population July 1, 1925, estimated	Chicken pox, cases reported	Diphtheria		Influenza		Measles, cases reported	Mumps, cases reported	Pneumonia, deaths reported
			Cases, estimated expectancy	Cases reported	Cases reported	Deaths reported
